EXECUTIVE SUMMARY

25

This Resource Conservation and Recovery Act (RCRA) Facility Investigation Work Plan has been prepared for Fort Stewart Military Installation, Georgia (Facility). The preparation of this RFI work plan (Phase I) is part of the requirements of the hazardous waste permit (HW-045 [S&T]) issued to Fort Stewart on August 14, 1987 and amended on September 27, 1989.

The purpose of this RCRA Facility Investigation (RFI) work plan (Phase I) is to document procedures to be utilized for RCRA investigations at 22 solid waste management units (SWMUs), consisting of potential sources of contamination identified at the Facility. Three of those 22 units (FST-004, FST-025, and FST-027) consist of more than one unit. Also the RFI plan (Phase I) outlines methods for evaluating exposure pathways and health risks associated with contamination that may be present. A multi-phased investigation is planned.

Phase I field investigations will include the installation of a minimum ground-water detection system at some of the sites. Ground water and soil sampling, preparation of maps, and interviews with installation personnel will be conducted. That information will be evaluated, along with existing data from past investigations to confirm if any releases have occurred. Based on the results of the Phase I field investigation, a Phase I RFI report will be submitted to the Georgia Environmental Protection Division (GA EPD) that summarizes the results of all work completed with recommendations for further investigation, if needed, or no further action, if warranted.

A Phase II investigation will be conducted at those sites, if any, where contamination is confirmed. The Phase II work will be based on the requirements that the GA EPD develops from their review of the Phase I RFI report.

Several quality assurance documents have been prepared which describe the procedures and protocols necessary for sample collection, sample analysis, and data validation. Included are checklists to be used for documenting the decision process and compliance to data quality objectives.

Additionally, this RFI work plan (Phase I) will be used as the foundation for site specific work plans prepared for investigations at selected SWMUs. The RFI work plan (Phase I) comprehensively applies to all RCRA investigations conducted at the Facility; the site specific plans

will precisely document field tasks for site characterization including sampling locations and analytical parameters; potential exposure pathways; concentration limits for chemicals of concern; and classification of potential remedial actions, if necessary.

27

1.0 INTRODUCTION

Fort Stewart, Georgia was issued a RCRA Part B permit (HW-045 [S&T]) on August 14, 1987, by GA EPD to store and treat hazardous waste. The initial RCRA Facility Assessment (RFA) completed in April 1987 (U.S. Army Environmental Hygiene Agency 1987), listed 25 total solid waste management units (SWMUs) with 9 requiring further action. On September 27, 1989, the hazardous waste permit was amended to include an expanded Section III on corrective action for SWMUs and other releases, specifying those units identified in the initial RFA which required a RCRA facility investigation (RFI). The amended permit listed 16 of the original SWMUs and 4 new units that would require an RFI. In June 1990, a supplemental RFA report was issued by the GA EPD that added 5 additional SWMUs to the list of 20. This resulted in a final list of twenty-five (25) SWMUs in the RFA Report submitted to GA EPD in June 1990. However, sites 14 and 22 of that list are the same site (FST-020). Therefore, the final number of SWMUs that require some type of RFI action is 24. 29

The detailed scope of work (SOW) to conduct a RFI, based on GA EPD's recommendations (Georgia Environmental Protection Division, 1988, 1989), was issued by the Army Corps of Engineers on August 17, 1990. The scope of work listed 24 total SWMUs, but excluded two units from this investigation. The sites not included in this work are the ~~FST-008 EOD Area and FST-013 which is the Fire Training Pit.~~ These sites are described in the April 1987 report prepared by the U.S. Army Environmental Hygiene Agency. The required work at these sites was conducted utilizing two other contracts. The work, as detailed in this RFI work plan (Phase I) for the remaining 22 SWMUs is to be conducted in a phased approach. The object of the Phase I Field Investigation is to determine if a release to the environment has occurred.

In the past, Fort Stewart, which is located approximately 34 miles southwest of Savannah, Georgia (Figure 1.1) has engaged in a variety of activities that may have resulted in the release of hazardous materials. These activities include landfill operations, open burning of timber and demolition debris, explosive ordinance disposal, fire-training exercises, hazardous waste storage, industrial waste-water treatment operations and sludge disposal, sewage treatment operations, radiator and battery shops, waste-oil storage and disposal, tanker purging operations, motor pools, recirculating wash impoundment, asphalt and diesel storage tanks.

All 22 SWMUs are located within Fort Stewart property boundaries (Plates 1 and 2) and have been designated as follows in the scope of work.

- South Central Landfill (FST-001)
- Camp Oliver Landfill (FST-002)
- Tac-X Landfill (FST-003)
- Burn Pits (FST-004A through FST-004G)
- EOD Area (FST-009)
- EOD Area (FST-010)
- EOD Area (FST 011)
- Current EOD Area (FST-012)
- Old Fire Training Pit (FST-014)
- DRMO Hazardous Waste Storage Area (FST-017)
- Industrial Waste-Water Treatment Plant (FST-018)
- Old Sludge Drying Beds (FST-019)
- Wright Air Field Sewage Disposal Beds (Land Spray Application and Lagoon) (FST-020)
- Radiator Shop (Building 1070) (FST-024A and FST-024B)
- 86 Waste Oil Tanks (FST-025)
- 724th Tanker Purging Station (FST-026)
- Motor Pools (Wash Racks, Grease Racks and Steam Racks) (FST-027)
- 724th Battery Shop (FST-028)
- Evans Army Heliport POL Storage Facility (FST-029)
- Recirculating Wash Impoundment ("Bird Bath") (FST-030)
- 3 DEH Asphalt Tanks (FST-031)
- Supply Diesel Tank (FST-032)

Previous work has addressed potential contamination at most sites including the following:

1. The 1982 ESE study of the potential for landfills to contaminate ground water, surface water, and air.

2. The 1983 ESE study of potential contamination at motor pools, radiator shops, fire fighting training areas, POL storage, industrial waste-water disposal, sanitary sewer systems, battery shop, landfills, and explosive ordnance disposal areas.
3. The 1987 U.S. Army Environmental Hygiene Agency Investigation of Soil Contamination at the fire training and explosive ordnance disposal areas.
4. The 1987 U.S. Army Environmental Hygiene Agency Investigation Evaluation of Solid Waste Management Units including the landfills, burn pits, EOD areas, fire training pits, DRMO HW storage area, IWTP sludge tanks, old sludge drying beds, sewage disposal bed, Wright Army Airfield waste POL point, radiator shop, and the waste oil tanks.
5. The 1988 U.S. Army Environmental Hygiene Agency Environmental Program Review including landfills, USTs, fire training pits, motor pools, burn pits, EOD areas, POL storage, DRMO, battery shop, sewage treatment plant, and the industrial waste-water treatment plant.

2.0 FACILITY DESCRIPTION AND HISTORY

2.1 Base History

Fort Stewart (named in honor of the Revolutionary War Brigadier General Daniel Stewart) was established in June 1940 as an Antiaircraft Artillery Center to prepare artillery troops for overseas deployment. Training activities associated with World War II (WWII) decreased by the end of 1944. Between January and September 1945, the installation operated as a Prisoner of War (POW) camp, housed two Italian units, and served as a separation center. The post was inactivated in September 1945 (ESE, 1983).

In August 1950, Fort Stewart was reactivated to train antiaircraft artillery units for the Korean Conflict. The training mission was expanded to include armor training concurrent with antiaircraft artillery training in 1953. In 1956, Fort Stewart was designated a permanent Army installation and an element of the U.S. Army Aviation School from Fort Rucker, Alabama. The aviation school was stationed there from 1966 to 1973 (ESE, 1983).

The 1st Battalion, 75th Infantry (Ranger) was activated at Fort Stewart on January 31, 1974. As a result, Fort Stewart became a training and maneuver area, providing tank, field artillery, helicopter gunnery, and small arms training for regular Army, USAR, and National Guard units. The 24th Infantry Division was permanently stationed at Fort Stewart in 1975 (ESE, 1983).

2.2 Meteorology

Fort Stewart has a humid subtropical climate with long hot summers. Average temperatures range from 50°F in the winter to 80°F in the summer. Average annual precipitation is 48 inches, with slightly over half falling from June through September. Prolonged drought is rare in the study area, but severe local storms (tornadoes and hurricanes) do occur. Under normal conditions, wind speeds rarely exceed 5 knots, but gusty winds of over 25 knots may occur during summer thunderstorms (Paulk, 1980).

2.3 Ecology

Approximately 7.811 square miles of the 436.815 square miles at Fort Stewart comprise the cantonment area. The remainder is used for ranges and training areas (~11 percent) or held as non-use areas.

Eighty-four percent of the land is forested (approximately 367.179 square miles). Sixty-six percent of this is pine forest with the major species including the slash pine, loblolly pine, and the longleaf pine. Thirty-four percent of the forest is composed of river bottom lands and swamps whose major species include the tupelo, other gum trees, water oak, and bald cypress trees. The open range and training areas comprise 11 percent of the base and consist of grasses, shrubs, and scrub tree (oak) growth.

Aquatic habitats on Fort Stewart include a number of natural or man-made ponds and lakes; the Canoochee River, Canoochee Creek and tributaries, and a number of bottom land swamps and pools. The Ogeechee River borders the installation along its northeast boundary. Organic detritus content is high and dark coloring of the water is not unusual. Dense growths of aquatic vegetation are also typical, especially during the summer months.

Both terrestrial and aquatic fauna are abundant in the unimproved areas of Fort Stewart. Major game species found on the installation include white-tailed deer, feral hog, wild turkey, rabbit, squirrel, and bobwhite in addition to numerous mammal, bird, reptile, and amphibian species (Environmental Science and Engineering 1983). Dominant fish include bluegill, largemouth bass, crappie, sunfish, channel catfish, minnows, and shiners. Three federally listed threatened or endangered species reside at Fort Stewart; the American alligator, Eastern indigo snake, and the red-cockaded woodpecker.

2.4 Hydrogeologic Setting

2.4.1 Regional Geology

Fort Stewart lies within the Southern Atlantic Lower Coastal Plain (Figure 2.1), with most surface elevations on the flat forested lands of the reservation ranging from 6 to 100 feet above mean sea level (msl). In the northwestern portion of the installation, the topographic relief is

greater with elevations ranging from 100 to 182 feet msl. The Canoochee River bisects the installation providing some topographic relief. About 60 percent of the eastern half of the installation is comprised of marshes and swamps with rolling hills formed by erosion. A small portion of the extreme western margin flows into the Altamaha River System by way of Beards Creek.

The principal surface waters on Fort Stewart drain into the Canoochee River which joins the southward-flowing Ogeechee River (part of the northeastern boundary of the reservation). A small portion of the extreme western margin flows into the Altamaha River System via Beard's Creek. Some streams along the eastern margin drain into the Ogeechee River while others along the southeastern margin flow southward to the Ochoopee, Jerico, and North Newport Rivers.

The lower Coastal Plain region of Georgia is underlain by a moderately thick wedge of unconsolidated and semi-consolidated sediments ranging in age from Recent to Cretaceous (Herrick and Vorhis, 1963). Generally, the sediments thicken and dip eastward toward the coast. The underlying Cenozoic Coastal Plain sediments are dominated by clastics (sand, silt, and clay) to the west, near the fall line, and become more carbonaceous (limestone and dolomite) near the coast (Herrick and Vorhis, 1963).

Ground water in the study area occurs within two major water-bearing zones, the surficial aquifer and the Floridan Aquifer. While these two systems are separate, under certain conditions, an exchange of water occurs between them (Environmental Science and Engineering 1982). Figure 2.2 shows the stratigraphic relationships of the aquifer systems near Fort Stewart.

2.4.2 The Surficial Aquifer

The surficial aquifer is under water-table conditions and is localized and discontinuous in distribution, ranging in depth from 2 to 10 feet below land surface to approximately 140 feet below land surface. Included in this aquifer are undifferentiated deposits of Pliocene to recent age.

The surficial sediments consist of poorly drained soils that have a sandy surface layer over loamy underlying layers (Looper 1982, Paulk 1980). The hydraulic conductivity of the surface soils range from 8.3×10^{-5} to 8.3×10^{-3} feet per second, with most values in the lower ranges. Beneath these soils lie the loose, generally structureless and massive, pale gray, buff and white,

undifferentiated, well sorted, fine to medium grained Holocene surficial sands that are up to 25 feet thick. The base of the aquifer sediments are undifferentiated, Miocene to Pleistocene paludal and lacustrine deposits composed of a higher clay and silt content than the surficial sediments (Huddleston 1989).

Ground water produced from the surficial aquifer is used primarily for domestic lawn and irrigation throughout most of the coastal areas. Wells screened in the surficial aquifer will yield from about 2 to 180 gallons per minute. The estimated transmissivity ranges from about 14 to 6,700 ft²/day. Tidal influences in the surficial aquifer generally occur east of the 20 foot topographic contour line; therefore, any fluctuations to the water table at Fort Stewart due to tidal influences would be minimal, occurring only in the eastern wetlands.

2.4.3 Floridan Aquifer

The principal regional and continuous aquifer in the area of Fort Stewart, Georgia is known as the Floridan Aquifer. The unit, composed of argillaceous sands and clays at the top with massive limestones at the base, is divided into the upper and lower Floridan Aquifers.

The geologic formations which constitute the upper Floridan Aquifer are the lower Hawthorn Group, the Oligocene Swannee Limestone (when present), the Oligocene Glendon Limestone (when present), the Oligocene Marianna Limestone (when present), and the upper Eocene Ocala Group. The thickness of the upper Floridan Aquifer ranges from less than 200 feet to 260 feet. Generally, this confined aquifer is shallowest near the northeastern part of the Georgia coast. In the area of Fort Stewart, the lower Middle Miocene Hawthorn Group's argillaceous sands and clays act as an upper confining unit for the Floridan Aquifer. The Oligocene Formations that may be present are the Swannee Limestone, the Glendon Limestone and the Marianna Limestone. These units consist of buff-colored, porous, limestone that contain foraminifera. The thickness of the Oligocene unit reaches about 120 feet, generally in the northeast, but is absent in other areas.

Beneath the Miocene or Oligocene sediments lies the upper Eocene Ocala Group. The Ocala is a massive, fossiliferous limestone that contains Bryzoan remains, foraminifera, and mollusk shells. Thicknesses of the Ocala Group range from 200 to 400 feet thick (Clarke et al 1990).

The upper Floridan Aquifer is most productive where it is thickest and where secondary permeability is most developed. The transmissivity of the aquifer in the Savannah area ranges from about 28,000 to 33,000 ft² per day (Krause and Randolph 1989). Pumping in the Savannah area is evenly distributed between industrial and public supply. Withdrawals in Savannah during 1986 were about 73 million gallons per day resulting in substantial cone of depression (Clarke et al 1990).

The lower Floridan Aquifer consists of Middle Eocene and older units. The estimated depth to the top of the aquifer is 450 feet in the Fort Stewart area (U.S. Army Environmental Hygiene Agency 1988). Usually the uppermost portion of the lower Floridan Aquifer is the most permeable (Clarke et al. 1990); however, ground water produced from this aquifer is brackish in this area.

2.5 Background Conditions

2.5.1 Ground-Water Quality

Ground-water quality on water samples from the deep artesian aquifer are provided in Appendix F of the assessment conducted by Environmental Science and Engineering (1983). As described in that report, water from the area is considered to be of good quality, has a relatively constant temperature, and is free of biological contamination and sediment. The water, which is moderately hard to hard, is treated by softeners; and, except for chlorination and fluoridation, it is otherwise untreated before use. Hydrogen sulfide is detectable in water supplies.

Ground-water samples are scheduled to be collected from a number of sites. At each site, samples will be collected from an upgradient well and analyzed in the same manner as the downgradient wells. The results of analysis for the downgradient wells will be compared to background levels and by either state or federal drinking water standards, naturally occurring concentrations as established in the upgradient well, or the method detection limits for those constituents not naturally occurring in ground water (i.e. volatile organics). The background levels will be set in accordance with 40 CFR 264.94 of Subpart F, Releases from Solid Waste Management Units.

53
53

2.5.2 Soils

The major soil types in the area of Fort Stewart Military Reservation were briefly described in two reports by Environmental Science and Engineering (1982 and 1983). A later description was provided in an environmental program review conducted by U.S. Army Environmental Hygiene Agency (1988). Briefly, the descriptions indicated that the soils ranged from well drained, nearly pure sand to poorly drained mixtures of loam, sand, and clay. The overall area is affected by seasonably high water table due to lower elevations and flat terrain. The soils lack natural strength and are vulnerable to erosion if denuded.

A soil investigation was conducted in March 1987, in which samples were collected in the Fire Training Areas and the EOD area (U.S. Army Environmental Hygiene Agency 1987). Background samples were collected from depths of 0 to 1 feet and 3 to 6 feet in Boring 9 collected at Zouck's Cemetery. The background sample indicated the following concentrations: mercury 0.398 to 0.399 ug/L, barium 1.99 to 6.19 ug/L, lead 3.98 to 35.9 ug/L, and arsenic at 3.99 ug/L. Chromium, cadmium, and selenium were all reported at below the method detection limit.

Soil samples collected during the RFI field investigation will be analyzed for volatile organic aromatics (EPA Method 8240), total petroleum hydrocarbons (EPA Method 8015), and TCLP. Background levels for each constituent identified will be determined from established state and federal levels.

The State of Georgia has established action levels for those constituents identified as present in soils by the analysis for TPH (EPA Method 8015) and volatile organic aromatics (EPA Method 8240). The Georgia action levels to be used during the investigation are 20 parts per million (ppm) BTEX (EPA Method 8240) and 100 ppm TPH, if a private water-well exists within a one-half mile radius or three miles of a public water well (Georgia Underground Storage Tank regulations). The action levels increase to 100 ppm BTEX and 500 ppm TPH where the water well sources are at distances greater than that mentioned above.

The concentrations of metals determined through the TCLP method will be compared to levels established in the federal regulations for the maximum concentrations of contaminants for toxicity characteristics. Those levels are provided in Table 1 of 40 CFR 261.24.

2.5.3 Surface Water

Water-quality data supplied for the Ogeechee River by the EPA was used to establish background conditions for surface waters in the area (Environmental Science and Engineering 1983). As reported in that document, the water is generally soft with a total hardness of 1.4 mg/L and an alkalinity of 14.2 mg/L. The values for the Canoochee River were slightly different with a hardness of 55 mg/L and an alkalinity of 6.4 mg/L. Background values for chlorides, nitrates, and sulfates as indicated in that report were approximately 6.0 mg/L, 0.04 mg/L, and 6.0 mg/L, respectively.

Surface-water samples are scheduled to be collected during Phase I field investigation of the RFI. Samples will be collected and analyzed, background samples will be collected from an upstream location to establish the approximate background levels.

2.6 Identification of Potential Receptors

A demographic profile of the area, according to the 1970 census, shows that the five-county area, encompassing Fort Stewart, has a population of 56,186 (Environmental Science and Engineering 1982). All of the land on the Fort Stewart Reservation is used for military operations. Although timber harvest is part of the multi-use function of army lands, it is not held in tracks for pulp and paper companies. All land is solely government owned in fee simple. Paper and pulp companies are the purchasers of the facility timber resources. Hunting is permitted and prominent on Fort Stewart land.

The major bodies of surface water on the facility are classified by the State of Georgia, in Table 2.1, as either fishing, possible fishing area if NPDES permit requirements are met, or recreational. Water sampling data (from previous testing) indicate that the State of Georgia criteria for fishing use are being met.

According to an Environmental Science and Engineering report (1983), range and training activities, along with operations at Fort Stewart, do not have a significant adverse effect on the biota. No fish kills due to unnatural toxic or hazardous materials have been documented, nor have stresses on vegetation or wildlife due to contaminant materials been recorded. Primary impacts on biota would include disturbance of soil and vegetation by vehicle maneuvers, clearing of areas for

development of ranges and training areas, and the physical and noise impacts of range firing and training upon vegetation and wildlife (Environmental Science and Engineering 1983). Localized habitat reductions, increased soil erosion and runoff, and the displacement of noise-sensitive wildlife would be results of these impacts. None of these elements are commonly or widely observed at Fort Stewart. In addition, a large percentage of Fort Stewart remains relatively undisturbed by noise or physical disturbance impacts.

Thirty one production wells are reportedly present at Fort Stewart: 9 in use, 20 unused, and 2 on standby (Figures 2.3 and 2.4). Five production wells, ranging in depth from 500 to 800 feet, provide water for the main cantonment area, (U.S. Army Environmental Hygiene Agency 1988). Outside of the cantonment area, Wright Army Airfield, Tac-X, and Camp Oliver each have one or more wells. The Fort Stewart well information is provided in Appendices 2.1 and 2.2. A water-quality engineering study was performed in 1976 by U.S. Army Environmental Hygiene Agency and is summarized in Tables 2.2 A&B.

The deeper wells in the area (surrounding counties) are used for drinking water, while the shallow wells are used for observation and other possible Army municipal uses. Some of the wells are not being used. The future usage of these wells probably will not change as the area is not being developed. However, Fort Stewart ground-water levels are affected by heavy ground-water use in the Savannah area. An average of 70 million gallons per day is pumped from the Floridan Aquifer by Savannah, equal to 98 percent of the ground-water demand in the area. The present rate of withdrawal exceeds the rate of recharge in the area (U.S. Army Environmental Hygiene Agency 1988).

3.0 PROJECT MANAGEMENT PLAN

3.1 Data Management Procedures and Guidelines

The data management for the Phase I RFI is designed to control, inventory, and track investigation data and document results. After data are generated by field and laboratory operations, it will be properly handled to maintain its integrity, the integrity of subsequent reports, and for future enforcement or legal actions. Data will be maintained using hardcopy (field logs, laboratory reports) and computer files. A central administrative file will be maintained by a designated "Document Custodian" at Geraghty & Miller, Inc.'s Jacksonville office. Field log books, chain-of-custody records, laboratory reports, photos, maps, correspondence, and reports will be maintained as part of the data record. The data management procedures outlined in this section are intended to provide for proper inventory, control, storage, and retrieval of data and information collected during the investigation. The various formats to be used to present the raw data and conclusions of the investigation are also discussed in this management plan. The sample labeling procedures, and other field documentations are discussed in the QAPP contained in Volume II, Attachment A. Chain-of-custody procedures are also discussed in the QAPP.

3.1.1 Records Control

Incoming investigation-related documents will be stamped with the date received and filed. If distribution is required, the appropriate copies will be made and distributed to project personnel. A listing of personnel intended to receive copies will be attached to the original document.

Information generated from field activities will be documented on the appropriate forms presented throughout the various sections of this RFI work plan (Phase I) and the QAPP. These include the following:

- Soil/coring log
- Well construction log
- Soil/sediment sampling log
- Drilling and sampling daily checklists
- Copies of field notes

Analytical documentation received from the laboratory will be retained and filed. Laboratory documentation will be maintained for purposes of validating the data collected during the investigation.

Notes from project meetings and telephone conversations also will be documented. A file of these notes will be maintained by the project coordinator. The project manager and the project coordinator will be responsible for reviewing and filing these documents as they are generated.

3.1.2 Document Filing and Access

Project files containing investigation-related data, transmittals, and reports generated during the investigation will be maintained at Geraghty & Miller, Inc.'s Jacksonville office according to the procedures outlined in this section. Access to the project files will be monitored and limited to project personnel.

A central file will be maintained in a secure, limited access area and under custody of the project manager. As soon as practical, incoming originals of correspondence, documents, and records will be placed in the project central file. The file shall include data, logs, field notes, pictures, QA/QC audit reports, progress reports, and other relevant records generated. Unless otherwise specified, the analytical laboratories will be required to maintain laboratory-generated documents for a period of three years after completion of the project.

Ongoing project data and reports will be distributed through the Army Corps of Engineers (ACOE), Savannah. The project manager will maintain a log of project documents forwarded to ACOE.

3.1.3 Computer Data Storage

During the implementation of this investigation, a large volume of various types of information will be compiled. Data related to the investigation will be stored in a computer database (either Excel or Lotus 123). This database will contain ground-water data collected during the Phase I RFI. When possible, data from the laboratory will be provided to Geraghty & Miller on a diskette as well as in hard copy. Well construction information from monitoring wells

installed during the Phase I RFI, together with new water-level data will be entered into the database. Soil-vapor data collected during this investigation will also be entered into the database. All information will be stored on hard drive with backup on double-sided, high density diskettes. The data files will be available to Fort Stewart upon request.

When required, data entry will be performed by designated Geraghty & Miller personnel. Computerized data bases will be checked against the original data (maintained in the project file) to determine if it was entered correctly. Data entered into the database system will be drawn from field records as well as laboratory analysis sheets. Data records will contain the following types of information:

- Unique sample or field measurement codes
- Sampling or field measurement location and sample or measurement type
- Sampling or field measurement raw data
- Laboratory analysis ID number (if appropriate)
- Property or component measured (including store code if applicable)
- Result of analysis (e.g., concentration)

3.1.4 Data Reduction Methods

Using the database-management system, data will be manipulated to provide integrated and detailed organization of the existing information. Data will be categorized and compiled according to information type to assist in defining the hydrogeologic system and existing contamination conditions. Information types may include: (1) geologic characterization, (2) hydraulic properties, (3) water-level data from wells and streams, (4) water-quality data, and (5) soil-vapor analyses.

The reduced data will be presented to the ACOE in either tabular or graphical formats. The following types of data will be presented in tabular format:

- Unsorted (raw) data;
- Results for each medium, or for each constituent monitored; and
- Summary data.

Other types of data that might be presented in an appropriate graphical format (e.g. bar graphs, line graphs, area or plan maps, isopleth plots, cross-sectional plots or transects, three dimensional graphs, etc.) are as follows:

- Sampling locations and sampling grids;
- Boundaries or sampling areas and areas where more data are required;
- Contamination levels, averages, and maxima;
- Geographical extent of contamination;
- Changes in concentration in relation to distance from the source, time, depth, or other parameters;
- Features affecting intramedia transport and potential receptors; and
- Ground-water elevation maps.

3.1.5 Project-Related Progress Reports

Monthly progress reports will be submitted to the ACOE. These progress reports will contain the following elements for each ongoing work activity.

- Identification of sites and activity
- Status of work at the sites and progress to date
- Difficulties encountered during the reporting period
- Actions being taken to rectify problems
- Activities planned for the next month
- Significant correspondence and telephone conversations
- Any significant contamination found will be summarized

3.2 Organization

The Geraghty & Miller personnel who have contributed to the preparation of the Phase I RFI work plan (Phase I) and who will have significant contribution to the Phase I RFI study are shown on the Phase I RFI Organizational Chart (Figure 3.1). Also included in the Phase I RFI Organizational Chart are the ACOE contact, and the types of subcontractors who will be participating in this project and providing support to Geraghty & Miller.

RFI PROJECT ORGANIZATION

Figure 3.1 RFI Project Organization

Client Name:

U.S. Army Corps of Engineers
Savannah District
Fort Stewart, Georgia

3.3 Schedule of Implementation

The schedule for implementation of the RFI work plan (Phase I) at the facility is shown on Figure 3.2. As indicated in that figure, it is anticipated that the GA EPD will review the RFI work plan (Phase I) in 45 days from receipt. Comments from the GA EPD to the RFI work plan (Phase I) will be incorporated within 2 weeks of receipt. Upon approval by the GA EPD to proceed, field activities will be initiated immediately and are anticipated to be completed within nine months. A preliminary Phase I RFI report will be completed within 30 days and submitted to the COE for review. Sixty days after that submittal, the Pre-final Phase I RFI report will be submitted to the GA EPD for review. Thirty days after receipt of the GA EPD comments, the final Phase I RFI report will be submitted.

Figure 3.2 Proposed Schedule for the Phase I Investigation of SWMUs, Fort Stewart, Georgia.

4.0 DESCRIPTION OF CURRENT SITE CONDITIONS AND PROPOSED WORK FOR THE PHASE I INVESTIGATION

The RFI work plan (Phase I) for the 22 SWMUs addressed in this document will be conducted in a phased approach. Phase I of the RFI is designed to utilize all existing information, the minimum detection system as required by the GA EPD, and additional investigations to confirm any releases present. The work proposed in this work plan, under the Phase I investigation, is based on the deficiencies and recommendations outlined in the GA EPD report titled "Site Characterization Review" (GA EPD, 1988). Because site conditions at a few units have changed considerably since this report was written, present conditions will be described and the work proposed will be based on the present conditions identified at those units. Documentation generated from past investigations will be used in conjunction with a combination of ground-water samples, soil samples, and interviews with personnel familiar with site histories to confirm if any releases have occurred and to make the necessary recommendations for further investigations, if needed. If no contamination is found at a SWMU further investigation is not anticipated. If contamination is confirmed, additional work as part of a Phase II investigation may be recommended in the Phase I RFI report in order to fully delineate the extent of any contamination identified. Table 4.1 summarizes the work effort at each site.

A description of the current conditions, including a site description and history, and a discussion of the nature and extent of the potential of contamination is given for each SWMU. The site description includes a brief introduction, site history, and reported site activities, previous investigations, and the nature and extent of potential of contamination. Based on this evaluation, recommendations for additional data needs and work are provided for each SWMU.

4.1 The South Central Landfill (FST-001)

4.1.1 Site Description and History

The South Central Landfill (FST-001) is located northwest of the main cantonment area of Fort Stewart. This 87-acre site (Figure 4.1) is situated on a point of land bounded on three sides (north, south, and west) by Mill Creek, a tributary to Taylors Creek, and Taylors Creek (see Figure 4.1). The landfill is currently active and has been in operation since 1940 (Environmental

Science and Engineering, 1982). The South Central Landfill's design and operation plan are shown in Figure 4.2.

According to the description provided in the Final Engineering Report (Environmental Science and Engineering, 1982), from 1940 to 1970, the eastern section of the landfill operated as a burn pit for garbage, paper waste, and construction debris. Other wastes included sludge from the waste-water treatment plant, waste air filters from the paint booth in the DOL Allied Trades Shop, dewatered sludge from the sewage treatment plant, autoclaved infectious wastes bagged in special containers and incinerator ash. From 1970 to 1982, the trench and fill method was used in the eastern part of the landfill. The operation moved west, restoring previously used land to forest land. Georgia's EPD determined that the trench method was unacceptable for this site because the water table is within 10 feet of the surface and the potential for movement of leachate to the ground water was possible (Environmental Science and Engineering, 1982). From 1982 to present, the area fill method was then used in the west section of the site.

4.1.2 Previous Investigations

Two previous reports were published regarding this site: (1) 1982 RCRA Final Engineering Report by Environmental Science and Engineering, and (2) 1983 Installation Assessment of Headquarters by Environmental Science and Engineering. Both of these reports, resulting from one investigation conducted in 1982, are referenced in the 1988 Environmental Program Review No. 32-24-7038-89 by the U.S. Army Environmental Hygiene Agency, the 1987 Hazardous Waste Consultation No. 37-26-1382-88, Evaluation of Solid Waste Management Units by the U.S. Army Environmental Hygiene Agency, and the 1989 RCRA Facility Assessment Report (RFA) by the EPD.

Six ground-water monitoring wells and seven observation wells were initially installed by the Corps of Engineers in January 1980 (Appendix 4.1 through 4.5). Ground-water analyses were conducted quarterly, as prescribed by the permit, until 1985. In 1985, the GA EPD reduced the monitoring requirement to annual analyses for chloride and specific conductance.

In 1982, Environmental Science and Engineering drilled 14 soil borings (Figure 4.3) to total depths of 50 feet, with two borings (SC-B1 and SC-B15) drilled to total depths of 100 feet. The purpose of these borings was to gather geotechnical information including soil descriptions

Table 4.1 Field Work and Laboratory Analyses Summary

91

SWMU NO.: FST-001

Description: Post-South Central Landfill

Tasks:

Collect water level data. Construct potentiometric map.
Sample ground water in 6 wells. Sample surface water.
Research ignition source.
Construct surface water flow map.
Construct cross-sections from available data.

Laboratory Analyses:

Type	EPA Method	Qty.	QA/QC	Total	Medium
pH, spc	various	8	2	10	GW/SW
VOCs	8240	8	3	11	GW/SW

and aquifer parameters. Subsequently, in 1983, Environmental Science and Engineering prepared the Installation Assessment. The purpose of this report was to determine the existence of toxic or hazardous materials and related contamination at Fort Stewart and Hunter AAF.

4.1.3 Waste Characterization

The waste characterization of the South Central Landfill (FST-001) includes garbage, paper waste, construction debris, sludge from the waste-water treatment plant, dewatered sludge from the sewage treatment plant, waste air filters from the paint booth in the DOL Allied Trades Shop, autoclaved infectious wastes bagged in special containers and incinerator ash (Environmental Science and Engineering 1982). A Fort Stewart engineer (personal communication with Thomas Houston) indicated that no fuel source was used in the burning of solid wastes at the landfill. The incinerator ash present was generated from solid waste burned at the three medical incinerators on base (medical, pathological and veterinarian). Although there is no evidence of release of contamination, Environmental Science and Engineering (1982) noted that leachate production was apparent as were numerous seeps into the trenches.

4.1.4 Potential for Releases/Known Releases

4.1.4.1 Ground Water

Six monitoring wells were sampled quarterly at this site from January 1980 until 1985 for the constituents approved by the GA EPD (Tables 4.2 and 4.3). The results from that previous analyses dated June 1980 are provided in Appendices 4.6 through 4.13. In 1985, the GA EPD reduced the monitoring requirements to annual analyses for chloride and specific conductance. Analytical results dated September 12, 1988, are provided in Appendix 4.6. The most recent analytical results from July and September 1989 and September 1990 are also provided in Appendix 4.6.

A potentiometric map was published at the site in 1982 by Environmental Science and Engineering (Figure 4.4). As indicated on this map, the general ground-water flow direction is from the southeast to northwest which agrees somewhat with the topographic map of the landfill (Figure 4.5). The 1982 Environmental Science and Engineering report also indicated that the vertical movement of ground water at the site appeared to be limited by partially cemented, silty,

4.5

fine sands present at an approximate depth of 30 feet. The permeability of this soil zone, as reported by Environmental Science and Engineering (1982), ranged from 10^{-6} to 10^{-8} cm/sec. Potential migration pathways are inferred to follow the ground-water flow direction.

The past analytical results indicated that only one parameter exceeded drinking water standards as set by the National Interim Secondary Drinking Water Regulations. Iron had been reported as present in concentrations that range from 1.2 ppm to 10.9 ppm, which are above the federal level of 0.3 ppm. The 1982, Environmental Science and Engineering report indicated that the sources for the high iron concentrations are the natural soils and the presence of iron waste products in the landfill. The remaining information collected at the South Central Landfill has indicated that there have been no releases to the uppermost aquifer at the site. However, because of the close proximity of the water table to the base of the landfill, the potential for a release to ground water is high.

4.1.4.2 Soil

Soil samples were taken at 5-foot intervals during the 1982 Environmental Science and Engineering survey. The soil pH in the zone just below the waste cells was generally found to be 6.0. This creates conditions conducive to heavy metal precipitation (Griffin et al. 1977). In some areas where construction debris was deposited, pH values were found to be much higher. The localized high soil pH zones are attributed to the concentration of alkali-rich materials (i.e. concrete) within specific and discontinuous zones of the soil column. A thick layer of clay was placed on the site and compacted to form the base of the landfill and serve to limit migration of leachate downward. The potential for impact by leachate to soil beneath the landfill and adjacent to the landfill is high.

4.1.4.3 Surface Water

Eight surface-water sampling locations, SC-S1 through SC-S8 were sampled in the 1982 Environmental Science and Engineering report (see Figure 4.2). Iron concentrations in the surface water reached maximum values in the vicinity of Sampling Station SC-S3, located near the intersection of Mill Creek and a drainage canal from the landfill. Concentrations dropped off significantly between SC-S3 and SC-S4, but stabilized at a value of approximately 2.1 ppm in the interval between SC-S5 and SC-S8.

The chemical data from the site indicated that the surface water in the area was not being significantly degraded by operation of the South Central Landfill. Although iron concentrations in the surface water near the landfill were high (1.09 ppm to 17.3 ppm), concentrations for iron near background values were reported a short distance from the landfill. Therefore, the potential for releases to surface water are low.

4.1.5 Proposed Work and Sample Analyses

4.1.5.1 General

Past investigations and ground-water monitoring of the landfill indicate no releases or impact to the environment. The landfill is currently regulated under a solid waste permit. The following work is proposed for the Phase I investigation.

- 1) All information pertaining to construction of the existing wells is provided in Appendices 4.1, 4.2, 4.3, 4.4, and 4.5.
- 2) Potentiometric and topographic maps are provided as Figures 4.4 and 4.5, respectfully.
- 3) One round of water-level data will be collected from the existing wells and used to determine the ground-water flow direction in accordance with procedures in the QAPP (Attachment A, Section 4.3.1). The rate of ground-water flow will be determined by tests conducted during the Phase II Investigation, if necessary.
- 4) The most recent water sampling data is provided in Appendices 4.6 through 4.13.
- 5) The existing six wells will be sampled and analyzed according to GA EPD recommendations for pH, specific conductance, volatile organic compounds (VOCs), RCRA metals, pesticides, PCBs, RA-226 and RA-228.

- 6) Two surface water samples (one upgradient and one downgradient) will be collected from Mill Creek (Figure 4.3) and analyzed according to GA EPD recommendations for pH, specific conductance, VOCs, RCRA metals, pesticides, PCBs, RA-226 and RA-228.
- 7) An attempt will be made to determine the ignition sources from 1940 to 1970 and what hazardous waste or hazardous waste constituents were present in the sludge and ash taken to the landfill. Information will be compiled from available sources and interviews with Fort Stewart personnel.
- 8) One representative north-south and one east-west cross section of the existing six monitoring wells in the south central landfill will be constructed using the information provided by Fort Stewart, and included within the final RFI report (Phase I).
- 9) Analytical results for metals, endrin, lindane, methoxychlor, toxaphene, 2, 4-D and 2,4,5-TP from samples collected at monitoring wells SCM-3 and SCM-5 are included in Appendix 6. The landfill permit does not require testing of the above constituents for other wells at the landfill; therefore analyses for the other wells are not available.
- 10) A surface water flow map will be included in the Phase I RFI report.

4.1.5.2 Field Sampling Plan

In accordance with the EPD's recommendations, the existing six wells will be sampled one time and the samples will be submitted for analyses of pH by EPA Methods 9040/9045, specific conductance by EPA Method 9050, VOCs by EPA Method 8240, RCRA metals by EPA Methods (6010 + 7470/7471 + 7060 + 7421 + 7740), pesticides and PCBs by EPA Method (8080), and RA-226/RA-228 by EPA Method 900. One upgradient and one downgradient surface water sample will be collected and analyzed for the same constituents as the six monitoring wells. If further drainage ditches are identified, than an additional upgradient and downgradient surface water sample for each drainage ditch will be collected and analyzed. One sample set will be submitted for laboratory duplication/split analysis. One equipment blank and one trip blank will be submitted for

QA/QC analysis. Field measurements for specific conductivity and pH will be recorded at each well. Refer to Table 6.1 for sampling summary. Field sampling procedures are found in the QAPP (Attachment A) and the Field Sampling Approach (Section 6.0). Additional sampling, if needed, will be proposed for the Phase II Investigation.

4.2 The Camp Oliver Landfill (FST-002)

4.2.1 Site Description and History

The Camp Oliver Landfill is located about 16 miles northwest of the cantonment area on State Highway 129, north of the Bivouac area (Figure 4.6). The landfill is located in an area of approximately 2 acres and is situated on the side of a small hill which slopes downward from south to north. There is approximately 25 feet of relief across the site. The landfill dimensions are 15 feet wide by 300 feet long by 5 to 6 feet deep. No surface evidence exists of a landfill or open dumping area except for some small dirt piles. Grass, small trees, and bushes now cover the area.

From the 1960s to 1979, the area was used for disposal of refuse from troop training activities and nearby residents by open pit burning. Although this landfill was officially closed in 1979, the trench method of solid waste disposal was still used, according to the Environmental Program Review (U.S. Army Environmental Hygiene Agency 1988). General refuse from ground maintenance activities and construction debris was dumped in the landfill from 1979 to 1984, during the annual 3 to 4-month training activities.

4.2.2 Previous Investigations

Two previous reports were published on this site: (1) 1982 RCRA Final Engineering Report by Environmental Science and Engineering, and (2) 1983 Installation Assessment of Headquarters by Environmental Science and Engineering. These reports resulted from one investigation conducted in 1982 and one investigation conducted January 17-21, 1983, respectively. The investigations are referenced in the 1988 Environmental Program Review No. 32-24-7038-89 by the USEAH, the 1987 Hazardous Waste Consultation No. 37-26-1382-88 Evaluation of Solid Waste Management Units by the USEAH and the 1989 RCRA Facility Assessment Report by GA EPD.

FIGURE
4.6

Four ground-water monitoring wells were installed in June 1980 by the Corps of Engineers (Figure 4.7). Ground water and surface-water samples were taken in 1980 (by the COE) and in 1981 by Environmental Science and Engineering. The results are included in Appendices 4.6 through 4.13. The upgradient well (CO-M1) has been broken off at the surface and CO-M4 cannot be found.

During the 1982 Environmental Science and Engineering investigation, five soil borings were completed to gather geotechnical data. Subsequently, Environmental Science and Engineering prepared the Installation Assessment Report in 1983. The purpose of this report was to determine the existence of toxic or hazardous materials and related contamination of Fort Stewart and Hunter AAF.

4.2.3 Waste Characterization

The waste characterization of the Camp Oliver Landfill include garbage and refuse, grass clippings, tree branches, root stumps, and chunks of asphalt and concrete. No evidence of disposal of toxic or hazardous wastes was found in the records searched by Environmental Science and Engineering (1982).

4.2.4 Potential for Releases/Known Releases

4.2.4.1 Ground Water

The two remaining monitoring wells were sampled in June 1980. The results of the 1980 analyses are provided in Appendices 4.6 through 4.13. The analytical results indicated that only one parameter exceeded drinking water standards as set by the National Interim Primary Drinking Water Regulations. Iron had been reported as present in concentrations that range from 0.684 ppm to 8.750 ppm, above the federal level of 0.3 ppm. The 1982 Environmental Science and Engineering report indicated that the sources for the high iron concentrations are the natural soils and the presence of iron waste products in the landfill.

The topography of the area is shown in Figure 4.7. A potentiometric map was prepared for the site in 1982 by Environmental Science and Engineering (Figure 4.8). As indicated by this map, ground-water flow direction is from southwest to northeast. According to the 1982

127

Environmental Science and Engineering report, it is very unlikely that the ground-water moves at anything other than a very low semi-saturated condition in the waste cells. Possible leachate formation would not move beyond the landfill boundary either horizontally or vertically (Environmental Science and Engineering 1982).

Information collected at the Camp Oliver Landfill has indicated that there have been no releases to the uppermost aquifer at the site. However, because of the close proximity of the water table to the base of the landfill, the potential for release to ground water is high.

4.2.4.2 Soil

Four soil borings (CO-B2 through CO-B5) were drilled to a depth of 50 feet with one boring drilled to a depth of 100 feet, during 1982 Environmental Science and Engineering study. The subsurface soils encountered by Environmental Science and Engineering were predominantly poorly sorted sands, silt/sand mixtures, and clay/sand mixtures. Soil borings from CO-B2 and CO-B5 and monitoring well CO-M2 encountered a coarse sand and gravel unit which extended from a depth of 10 feet to the bottom of the borings at 50 feet (Environmental Science and Engineering 1982). This highly permeable unit appeared to be a linear feature primarily upgradient. As determined from existing data, the potential for impact to adjacent surface soils is low. However, the potential for impact by leachate to soil directly beneath the landfill is high.

4.2.4.3 Surface Water

Surface-water samples were collected at two sampling locations, CO-S1 (upstream) and CO-S2 (downstream) as indicated in the 1982 Environmental Science and Engineering report (see Figure 4.7). The results of analysis indicated that fecal coliform was detected at the two surface-water sampling sites. This was attributed to public fishing use and Army personnel use (Environmental Science and Engineering 1982). Iron concentrations in the surface water near the landfill were reported as high (1.35 to 2.83 ppm), however, concentrations near background values for iron were reported a short distance downstream from the landfill.

The 1982 Environmental Science and Engineering report indicated that possible leachate is contained and/or attenuated on the site. Chemical data from the site indicated that the surface water

in the area was not being significantly degraded by the previous operation of the Camp Oliver Landfill. Therefore, the potential for releases to surface water is low.

4.2.5 Proposed Work and Sample Analyses

4.2.5.1 General

The following work is proposed for the Phase I investigation of the Camp Oliver Landfill (FST-002):

- 1) Four groundwater monitoring wells were constructed in 1980. The upgradient well has been broken off at the surface and CO-M4 could not be found. The other two monitoring wells appear to be in good condition. The wells were constructed with 4 inch PVC well casing and the concrete pads are intact.
- 2) Existing topographic and potentiometric maps are submitted for review (see Figures 4.7 and 4.8).
- 3) All existing well construction information is submitted for review (Appendix 4.7).
- 4) The surface and ground-water analyses already performed are submitted (Appendices 4.6 through 4.13).
- 5) The existing upgradient well will be abandoned per GA EPD recommendations.
- 6) Two new wells will be installed to replace two of the 1980 wells. They will be constructed near the former wells.
- 7) The existing and new wells will be sampled and analyzed according to GA EPD recommendations for pH, specific conductance, VOCs, RCRA metals, pesticides, and PCBs.

- 8) One upgradient and one downgradient surface water sample will be collected from Canoochee Creek and analyzed according to GA EPD recommendations for pH, specific conductance, VOC, RCRA metals, pesticides, and PCBs.
- 9) Well protection will be installed at all four wells to include locking well covers and protective posts at the corners of the well pads, approximately 2 feet in height.
- 10) One round of water-level data will be collected and used to determine ground-water flow direction. The rate of movement will be determined in Phase II, if necessary.
- 11) One representative north-south and one east-west cross section of the four monitoring wells in the Camp Oliver Landfill will be constructed using the information provided by Fort Stewart, and included within the Phase I RFI report (Phase I).
- 12) A surface water flow map will be included in the Phase I RFI report.

4.2.5.2 Soil Boring and Monitor-Well Installation Plan

Geraghty and Miller will install two ground-water monitoring wells (to replace CO-M1 and CO-M4). The monitoring wells will be installed by drilling with a rig (hollow-stem auger method). Proposed well placement is shown in Figure 4.7. The monitoring wells will be installed with a 10 foot screen to a depth of 5-8 feet into the saturated zone of the surficial sand aquifer in accordance with the Field Sampling Approach (Section 6.0). Well protection around each well will be installed to include concrete pads, protective casing, locking well covers, and protective posts at the corners of the well pads. The existing upgradient well will be abandoned in accordance with the Field Sampling Approach, Section 6.0.

4.2.5.3 Field Sampling Plan

In accordance with the GA EPD's recommendations, the four wells will be sampled one time and samples will be submitted for analyses of VOCs by EPA Method 8240, pesticides and PCBs by EPA Method 8080, RCRA metals by EPA Methods 6010 + 7470/7471 + 7060 + 7421 + 7740, pH by EPA Methods 9040/9045, and specific conductance by EPA Method 9050. One

upgradient and one downgradient surface water sample will be collected and analyzed for the same constituents as the 4 monitoring wells. If further drainage ditches are identified, than an additional upgradient and downgradient surface water sample for each drainage ditch will be collected and analyzed. Field measurements for specific conductivity and pH will be recorded at each well. Refer to Table 6.1 for sampling summary. Field sampling will follow procedures found in the QAPP (Attachment A) and the Field Sampling Approach (Section 6.0). Additional sampling, if needed, will be proposed for the Phase II investigation.

4.3 The Tac-X Landfill (FST-003)

4.3.1 Site Description and History

The Tac-X Landfill (FST-003) is located about 1 1/4 miles south of the installation's northern boundary and 3 1/2 miles south-southwest of the city of Pembroke (Figure 4.9). The 5-acre site lies one mile southeast of Tac-X (Noncommissioned Office Academy) helicopter training area off of Fort Stewart Highway 42. Dimensions of the old trench are 20 feet wide by 400 feet long by 5 to 6 feet deep (U.S. Army Environmental Hygiene Agency 1988). According to the U.S. Army Environmental Hygiene Agency report, general physical conditions at the site showed a trench-like depression where the dump once existed, some aged refuse protruding from the soil at the bottom of the depression, grass, water and mud on the bottom of the depression, while grass, trees, and bushes covered the entire area. The site is essentially flat (less than 7 feet relief) and slopes from north to south.

From the 1960s to 1979, the area used open pit burning and trench fill for disposal of garbage from troop training activities, and from nearby residents. In 1979, the landfill was officially closed. The trench fill method was still used from 1979 to 1982 for disposal of general refuse from ground maintenance activities.

4.3.2 Previous Investigations

Two previous reports were published regarding this site: (1) 1982 RCRA Final Engineering Report by Environmental Science and Engineering, and (2) 1983 Installation Assessment of Headquarters by Environmental Science and Engineering. One of these reports was a result of an investigation conducted in 1982 and one was a result of an investigation conducted

January 17-21, 1983, respectively. The investigations are referenced in the 1988 Environmental Program Review No. 32-24-7038-89 by the U.S. Army Environmental Hygiene Agency (USAEH), the 1987 Evaluation of Solid Waste Management Units by the U.S. Army Environmental Hygiene Agency, and the 1989 RCRA Facility Assessment Report (RFA) by the EPD.

Two ground-water monitoring wells (TX-M1 and TX-M3) and two observation wells (Figure 4.10) were installed in June 1980 by the COE (Appendices 4.1 through 4.5). Ground water and surface-water samples were collected in June of 1980. During 1982, Environmental Science and Engineering drilled four soil borings (TX-B1 through TX-B4) to a depth of 50 feet, with one boring (TX-B5) drilled to a depth of 100 feet (see Figure 4.10). The purpose of these borings was to gather geotechnical information including soil descriptions and aquifer parameters. Subsequently in 1983, Environmental Science and Engineering prepared the Installation Assessment Report. The purpose of this report was to determine the existence of toxic or hazardous materials and related contamination at Fort Stewart and Hunter AAF.

4.3.3 Waste Characterization

The waste characterization of the Tac-X Landfill from the 1960s to 1979, includes residential waste, food cans, brush, plastic, and cardboard boxes. From 1979 to 1982, the wastes included grass clippings, tree branches, root stumps, and chunks of asphalt and concrete.

4.3.4 Potential for Releases/Known Releases

4.3.4.1 Ground Water

Two monitoring wells were sampled at the landfill in June 1980 by the COE. The results from that analyses are provided in Appendices 4.6 through 4.13. The analytical results indicated that only one parameter exceeded drinking water standards set by the National Interim Primary Drinking Water Regulations. Iron had been reported as present in concentrations that range from 0.613 ppm to 10.2 ppm which are above the federal level of 0.3 ppm. The 1982 Environmental Science and Engineering report indicated that the sources for the high iron concentrations are the natural soils and the presence of iron waste products in the landfill.

RCRA FACILITY INVESTIGATION
TAC-X - TOPOGRAPHY, MONITOR WELL, & SOIL BORING MAP FST-003
FORT STEWART
GEORGIA

FIGURE
4.10

The topography of the site is shown in Figure 4.10. A potentiometric map was prepared for the site in 1982 by Environmental Science and Engineering (Figure 4.11). Ground water flows from the north-northeast to south-southwest, as indicated on this map.

Information collected at the Tac-X Landfill has indicated that there has been no releases to the uppermost aquifer at the site. However, because of the close proximity of the water table to the base of the landfill, the potential for a release to ground water is high.

4.3.4.2 Soil

Four soil borings (TX-B1 through TX-B4) were drilled to a depth of 50 feet, with one boring (TX-B5) drilled to 100 feet during the 1982 Environmental Science and Engineering investigation (see Figure 4.10). According to the 1982 survey, the following was noted: (1) Subsurface sediments encountered were predominantly fine grained to coarse grained sands and sand-silt mixture. A gravel pocket was encountered at 20 feet in Well TX-M2. (2) Although the gravel is capable of transmitting ground water at a high rate, the low permeability sand-silt soils surrounding it severely restrict the movement of ground water. (3) The permeability of the soils below the solid waste cell is very low, ranging from 10^{-7} to 10^{-8} cm/sec. (4) Soil pH was generally above 5.0, which creates conditions conducive to heavy metal precipitation. Information provided indicated that leachate was observed trickling from the landfill. During a recent site visit by COE personnel, no leachate was observed. Based on the past investigations, the potential for impact by leachate to soil beneath the landfill is considered high, although the potential for impact to soils adjacent to the landfill is low.

4.3.4.3 Surface Water

Two surface-water sampling locations (TX-S1 and TX-S2) were sampled in the 1982 Environmental Science and Engineering investigation (see Figure 4.10). The results from the analyses of the 1982 survey are provided in Appendices 4.6 through 4.13. Chemical data from the site indicated that the surface water in the area is not being significantly degraded by the past operation of the Tac-X Landfill. Although iron concentrations in the surface water near the landfill were reported high (0.613 to 10.2 ppm), concentrations near background values for iron were reported a short distance from the landfill. Therefore, the potential for releases to surface water is low.

4.3.5 Proposed Work and Sample Analyses

4.3.5.1 General

The following work is proposed for the Phase I investigation at the TAC-X Landfill (FST-003):

- 1) Four wells were constructed here in 1980 (TX-M1, TX-M2, TX-M3, and TX-M4). These appear to be in good condition.
- 2) Existing topographic and potentiometric maps are submitted as Figures 4.10 and 4.11.
- 3) Surface and ground-water analyses already performed are submitted in Appendices 4.6 through 4.13.
- 4) The existing well construction information will be submitted in the Phase I RFI report.
- 5) Submit analysis of leachate, if found. If this is not possible, a suitable substitute sample of leachate (if possible) or of soil or surface water will be analyzed for pH, specific conductance, VOCs, RCRA metals, pesticides, and PCBs.
- 6) The general ground-water flow direction at the site will be determined. The rate of flow will be determined in Phase II, if necessary.
- 7) The existing wells will be sampled per GA EPD recommendations for pH, specific conductance, VOCs, RCRA metals, pesticides and PCBs.
- 8) Well protection for the existing wells will be installed to include protective casing, locking well covers, and protective posts at the concrete well pads.
- 9) One representative north-south and one east-west cross section of the 4 existing wells in the Tac-X Landfill will be submitted in the Phase I RFI report.

- 10) A brief description of the present site conditions will be provided.
- 11) Soil permeability tests are included in Appendix 4.12. The soil permeability will be investigated further, if necessary.
- 12) One upgradient and one downgradient surface water sample will be collected from Otter Hole Branch Pond and analyzed according to GA EPD recommendations for pH, specific conductivity, VOC, RCRA metals, pesticides, and PCBs.
- 13) A surface water flow map will be included in the Phase I RFI report.

4.3.5.2 Field Sampling Plan

In accordance with the GA EPD's recommendations, leachate from the landfill will be sampled one time and analyzed for pH by EPA Methods 9040/9045, specific conductance by EPA Method 9050, VOCs by EPA Method 8240, RCRA metals by EPA Methods 6010 + 7470/7471 + 7060 + 7421 + 7740, and pesticides and PCBs by EPA Method 8080. A duplication/split analyses will be run on the samples collected. Field measurements for specific conductivity and pH will be recorded for each sample.

The existing four wells will be sampled and analyzed for pH by EPA Method 9040/9045, specific conductance by EPA Method 9050, VOCs by EPA Method 8240, RCRA metals by EPA Methods 6010 + 7470/7471 + 7060 + 7421 + 7740, and pesticides and PCBs by EPA Method 8080. One trip blank will be submitted for QA/QC analysis. One upgradient and one downgradient surface water sample will be collected and analyzed for the same constituents as the four monitoring wells. If further drainage ditches are identified, than an additional upgradient and downgradient surface water sample for each drainage ditch will be collected and analyzed. Field measurements for specific conductivity and pH will be recorded for each sample. Refer to Table 6.1 for sampling summary. Field sampling will follow procedures found in the QAPP (Attachment A) and the Field Sampling Approach (Section 6.0). Additional wells, if needed, will be proposed in the Phase II Investigation.

4.4 The Burn Pits (FST-004A to FST-004G)

4.4.1 Site Description and History

Seven separate burn pits are located around the cantonment area as shown in Figures 4.12 (Burn Pits A, B, C, and D) and 4.13 (Burn Pits E, F, and G). Six were used (Burn Pits A, B, C, D, E, and F) and are subject to the RFI. Burn Pit G was cleared but was never used. The six burn pits used, presumably have been in existence since the beginning of Fort Stewart operations and have been used at various times to burn combustible solid waste (i.e. construction debris, tree limbs, etc.). The sites differ in location and size. A topographic map is provided on the six sites that were used.

Burn Pit A (10± acres) is located approximately 1200 feet southwest of Fort Stewart, Route 38 from the junction of Fort Stewart 40 and Fort Stewart 38 (Figure 4.14). Burn Pit B (3± acres) is located approximately 200 feet northeast on Fort Stewart 90 from the junction of Fort Stewart 90 and the cutoff to State Route 196 (Figure 4.15). Burn Pit C (7± acres) is located approximately 300 feet west on Fort Stewart 90 from the junction of 15th Street and Fort Stewart 90 (Figure 4.16). Burn Pit D (10± acres) is located approximately 500 feet west on Fort Stewart 90 from the junction of Fort Stewart 90 and 6th Street (Figure 4.17). Burn Pit E (1± acre) is located approximately 800 feet east of Fort Stewart 144 from the junction of Fort Stewart 144 and Fort Stewart 50 (Figure 4.18). Burn Pit F (3± acres) is located approximately 3400 feet south on Fort Stewart 51 from the junction of Fort Stewart 51 and State Route 144 (Figure 4.19). Burn Pit G (never utilized) is located near the junction of Fort Stewart 51 and US 82.

Currently, five of the burn pits are inactive and have not been used for some time (Burn Pits B, C, D, E and, F). The actual time of operation is undetermined. Burn Pit A was observed being used during the initial site visit (November 1, 1990).

4.4.2 Previous Investigations

No previous investigations have been conducted at Fort Stewart that characterize the nature of the burn pits or any releases to the environment that may have occurred. However, two previous reports describing the SWMUs at Fort Stewart (U.S. Army Environmental Hygiene

Agency 1988 and U.S. Army Environmental Hygiene Agency 1987) did mention the burn pits. No detailed investigations were conducted or mentioned in those reports.

4.4.3 Waste Characterization

The waste characterization of Burn Pits A through F include scrap lumber, timber cuttings, dumping construction and demolition waste, ashes, concrete trunks, and dirt from excavations. Personal communication with employees of Fort Stewart (pers. comm. Tommy Houston 1990) indicated that no fuels or solvents were used as ignition sources at these burn pits.

4.4.4 Potential for Releases/Known Releases

The RFA report indicated that no evidence of a release to the environment was apparent. However, it was also mentioned that if contaminants were present, the likely migration pathway would be to ground water. No ground-water monitoring wells have been installed at these sites and no past sampling has been conducted to characterize and verify releases to the environment.

4.4.5 Proposed Work and Sample Analyses

4.4.5.1 General

The following work is proposed for the Phase I investigation at Burn Pits FST-004A through FST-004G:

- 1) A minimum ground-water detection system is needed at six of the sites. Four wells will be installed at each site and sampled according to GA EPD recommendations. The samples will be analyzed for pH, specific conductance, VOCs, and RCRA metals.
- 2) A topographic survey was done in August 1990 by the COE at the six sites. Boring locations and other required information will be added to the maps and will be submitted in the Phase I RFI report.

- 3) One round of water-level data will be collected and used to determine ground-water flow direction. A potentiometric map of each site will be constructed. The rate of ground-water flow will be determined by tests in the Phase II investigation, if necessary.
- 4) Site FST-004G was cleared but never used as a burning area. It presently is grown over with small trees, brush, small palmettos, and grass. A detailed description of this site and the fact that it was never used will be prepared and submitted in the Phase I RFI report.

4.4.5.2 Soil Boring and Monitor-Well Installation Plan

Geraghty and Miller will install four ground-water monitoring wells at each burn pit (FST-004A through FST-004F) for a total of 24 wells. The hollow-stem auger method will be utilized to install the wells. Proposed well placement is shown in Figures 4.14-4.19. The monitoring wells will be installed with a 10 foot screen to a depth of 5-8 feet into the saturated zone of the surficial sand aquifer in accordance with the Field Sampling Approach (Section 6.0). Well protection around each well will be installed to include concrete pads, protective casing, locking well covers, and protective posts at the corners of the well pads. The existing upgradient well will be abandoned in accordance with the Field Sampling Approach, Section 6.0.

4.4.5.3 Field Sampling Plan

In accordance with the GA EPD's recommendations, the 24 wells will be sampled once and the samples will be submitted for analyses of VOCs by EPA Method 8240, RCRA metals by EPA Methods 6010 + 7470/7471 + 7060 + 7421 + 7740, pH by EPA Methods 9040/9045, and specific conductance by EPA Method 9050. One extra sample will be collected for lab duplication/split analysis. One equipment blank and two trip blanks will be submitted for QA/QC analysis. Field measurements for specific conductivity and pH will be recorded for each sample set in the field. Refer to Table 6.1 for sampling summary. Field sampling will follow procedures found in the QAPP (Attachment A) and the Field Sampling Approach (Section 6.0). The Phase I Report will include recommendations for the Phase II Investigation, if any.

4.5 The EOD Area (FST-009)

4.5.1 Site Description and History

EOD Area FST-009 is located 11 miles north of the cantonment area and 1 mile east of Georgia Highway 119 (Figure 4.20) in designated area B-12 (Figure 4.21) on the Fort Stewart Military Installation Map. EOD Area FST-009 was operated from 1979 to 1983 where open detonation of unexploded ordnance took place. There are three blast craters occupying a total area of approximately 2 acres. As indicated in the initial RFA (U.S. Army Environmental Hygiene Agency 1988), the craters in the ground contained no solid waste, other than small bits of shrapnel and no evidence of ashes or charred ground from the explosions.

4.5.2 Previous Investigations

EOD Area FST-009 was previously investigated as part of the initial RFA by U.S. Army Environmental Hygiene Agency in April 1987. The results from that investigation were referenced in two subsequent documents: 1) the 1988 Environmental Program Review No. 32-24-7038-89 by the U.S. Army Environmental Hygiene Agency, and 2) Evaluation of Solid Waste Management Units by the U.S. Army Environmental Hygiene Agency.

Soil sampling conducted by U.S. Army Environmental Hygiene Agency during the 1987 study was performed at EOD Area FST-009 (Figure 4.22). As indicated in the initial RFA (U.S. Army Environmental Hygiene Agency, 1988), laboratory analyses (Appendix 4.16) on the soil indicated no significant soil contamination.

4.5.3 Waste Characterization

The waste characterization of the EOD Area FST-009 as indicated in the initial RFA (USEAH 1988) includes excess artillery powder bags, small arms rounds, artillery and mortar rounds, illuminating projectiles, pyrotechnics, bulk explosives, rockets, propellant, and regular and smoke grenades. According to EOD personnel, there are no records or information indicating any disposal of CB agents, acids, solvents, or other hazardous or toxic substances in the EOD area (Environmental Science and Engineering 1983).

4.5.4 Potential for Releases/Known Releases

During the U.S. Army Environmental Hygiene Agency 1987 soils survey, sampling crews conducted a transect across EOD Area FST-009 collecting 10 samples at 40-foot intervals, each oriented to intersect as many craters as possible. The crew limited soil sampling to the uppermost 1 inch of soil due to the safety precautions associated with unexploded ordnance. The samples were analyzed for metals using total digestion procedure (total metals) and the Toxicity Extraction Procedure (EP Tox).

Metals analysis from the 1987 United States Army Environmental Hygiene Agency survey of the samples collected at EOD Area FST-009 are presented below (Appendix 4.16). As indicated in that report, the analysis for total metals showed the existence of various levels of arsenic (3.91 to 12.9 ppm), barium (5.33 to 11.5 ppm), mercury (0.368 to 0.429 ppm), and lead (30.1 to 116.0 ppm) in all of the samples. These metals were also found in the background samples in approximately the same concentration. The conclusion drawn were that these metals may be indigenous to the soils of this area. Other metals reported in those samples were selenium to 0.259 ppm (1 of 10 samples), total chromium ranging from 4.55 to 4.78 ppm (3 of 109 samples), and cadmium ranging from 1.84 to 25.4 ppm (8 of 10 samples). The report went on to say that the analysis for EP Tox metals failed to reveal the existence of any of these compounds above the detection limit of the analysis. The conclusion of the investigation reported that although the metals were present, the compounds are not leachable as defined by the EP Tox, and as a result, are not mobile in the soil posing no risk to human health or the environment.

4.5.5 Proposed Work and Sample Analyses

4.5.5.1 General

The following work is proposed for the Phase I investigation at EOD Area (FST-009):

- 1) Soil sample data from April 1987 is submitted in Appendix 4.16.
- 2) A map will be prepared showing locations and depth of the samples.

- 3) Soil samples will be collected in the approximate location of the blast craters and analyzed according to GA EPD recommendations for pH, specific conductance, RCRA metals, and explosive residue.
- 4) The need for ground-water monitoring wells will be determined from data collected during the Phase I investigation and may be recommended for Phase II.

4.5.5.2 Field Sampling Plan

Surface soils in the blast craters will be sampled at five locations in EOD area FST-009 and analyzed for pH by EPA Methods 9040/9045, specific conductance by EPA Method 9050, RCRA metals by EPA Methods 6010 + 7470/7471 + 7060 + 7421 + 7740, and explosive residue by EPA Method 8350. One additional background sample will be collected and analyzed for the same parameters. One equipment blank will be submitted for QA/QC analysis. One extra sample will be collected for lab duplication/split analysis. Refer to Table 6.1 for sampling summary. Field sampling will follow procedures found in the QAPP (Attachment A) and the Field Sampling Approach (Section 6.0). The need for ground-water monitoring or additional sampling will be proposed and completed during Phase II.

4.6 The EOD Area (FST- 010)

4.6.1 Site Description and History

EOD Area FST-010 is located 4 miles north of the cantonment area and 1 mile east of Georgia Highway 119 (see Figure 4.20) in designated Area B-8 (Figure 4.23) on the Fort Stewart Installation Map. EOD Area FST-010 was operated from 1975 to 1980 where open detonation of unexploded ordnance took place. There is one trench with a total area of 2 acres. As indicated in the initial RFA (U.S. Army Environmental Hygiene Agency 1988), the craters in the ground contained no solid waste, other than small bits of shrapnel, and no evidence of ashes or charred ground from the explosions.

4.6.2 Previous Investigations

EOD Area FST-010 was previously investigated as part of the initial RFA by U.S. Army Environmental Hygiene Agency in April 1987. The results from that investigation were referenced in two subsequent documents: 1) the 1988 Environmental Program Review No. 32-24-7038-89 by the U.S. Army Environmental Hygiene Agency, and 2) Evaluation of Solid Waste Management Units by the U.S. Army Environmental Hygiene Agency.

Soil sampling conducted by U.S. Army Environmental Hygiene Agency during the 1987 study was performed at EOD Area FST-010 (Figure 4.24). As indicated in the initial RFA (U.S. Army Environmental Hygiene Agency, 1988), laboratory analyses (Appendix 4.16) on the soil indicated no significant soil contamination.

4.6.3 Waste Characterization

The waste characterization of the EOD areas as indicated in the initial RFA (USEAH 1988) includes excess artillery powder bags, small arms rounds, artillery and mortar rounds, illuminating projectiles, pyrotechnics, bulk explosives, rockets, propellant, and regular and smoke grenades. According to EOD personnel, there are no records or information indicating any disposal of CB agents, acids, solvents, or other hazardous or toxic substances in the EOD area (Environmental Science and Engineering 1983).

4.6.4 Potential for Releases/Known Releases

During the U.S. Army Environmental Hygiene Agency 1987 soils survey, sampling crews conducted a transect across EOD Area FST-010 collecting 10 samples at 40-foot intervals, each oriented to intersect as many craters as possible. The crew limited soil sampling to the uppermost 1 inch of soil due to the safety precautions associated with unexploded ordnance. The samples were analyzed for metals using total digestion procedure (total metals) and the EP Tox.

Metals analysis from the 1987 U.S. Army Environmental Hygiene Agency survey of the samples collected at EOD Area FST-010 are presented below (Appendix 4.16). As written in that report, the analysis for total metals showed the existence of various levels of arsenic (1.98 to 9.91 ppm), barium (9.72 to 50.6 ppm), mercury (0.394 to 0.400 ppm), and lead (97.8 to 3281.0 ppm)

in all of the samples. These metals were also found in the background samples in approximately the same concentration. Only, the lead data revealed results which were significantly higher than the concentration in the background samples. The report also indicated that, other metals found in these samples were selenium to 0.257 ppm (1 of 9 samples), total chromium ranging from 9.00 to 10.4 ppm (2 of 9 samples), and cadmium ranging from 1.98 to 26.0 ppm (3 of 9 samples). The analysis for EP Tox metals failed to reveal the existence of any of these compounds above the detection limit of the analysis. The conclusions drawn were that although the compounds existed in the soil, they were not leachable as defined by the EP Tox. The report indicated that the compounds were not mobile in the soil and did not pose a risk to human health or the environment.

4.6.5 Proposed Work and Sample Analyses

4.6.5.1 General

The following work is proposed for the Phase I investigation at EOD Area (FST-010):

- 1) The soil sample data from April 1987 is submitted in Appendix 4.14.
- 2) A map will be prepared showing locations and depth of the samples.
- 3) Soil samples will be collected in the approximate location of the blast craters and analyzed according to GA EPD recommendations for pH, specific conductance, RCRA metals, and explosive residue.
- 4) The need for ground-water monitoring wells will be determined from data collected during the Phase I investigation and may be recommended for Phase II.

4.6.5.2 Field Sampling Plan

Surface soils in the blast craters will be sampled at five locations in EOD area FST-010 and analyzed for pH by EPA Methods 9040/9045, specific conductance by EPA Method 9050, RCRA metals by EPA Methods 6010 + 7470/7471 + 7060 + 7421 + 7740, and explosive residue by EPA Method 8350. One additional background sample will be collected and analyzed for the same parameters. Refer to Table 6.1 for sampling summary. Field sampling will follow procedures

found in the QAPP (Attachment A) and the Field Sampling Approach (Section 6.0). The need for ground-water monitoring or additional sampling will be proposed and completed during Phase II.

4.7 EOD Area (FST-011)

4.7.1 Site Description and History

EOD Area FST-011 is located 3 miles northeast of the cantonment area, about 2 miles south of Georgia Highway 144 and 1 mile northeast of Wright Army Airfield (see Figure 4.20) in designated Area A-16 on the Fort Stewart Military Installation Map (Figure 4.25). EOD Area FST-011 was operated from 1953 to 1975 where open detonation of unexploded ordnance took place. There are numerous blast craters spread out over nearly 10 acres. As indicated in the initial RFA it is difficult to distinguish this site from the surrounding forest since it has become overgrown with trees and bushes.

4.7.2 Previous Investigations

EOD Area FST-011 was previously investigated as part of the initial RFA by U.S. Army Environmental Hygiene Agency in April 1987. The results from that investigation were referenced in two subsequent documents: 1) the 1988 Environmental Program Review No. 32-24-7038-89 by the U.S. Army Environmental Hygiene Agency, and 2) Evaluation of Solid Waste Management Units by the U.S. Army Environmental Hygiene Agency.

Soil sampling conducted by U.S. Army Environmental Hygiene Agency during the 1987 study was performed at EOD Area FST-011 (Figure 4.26). As indicated in the initial RFA (U.S. Army Environmental Hygiene Agency, 1988), laboratory analyses (Appendix 4.16) on the soil indicated no significant soil contamination.

4.7.3 Waste Characterization

The waste characterization of the EOD areas as indicated in the initial RFA (USEAH 1988) includes excess artillery powder bags, small arms rounds, artillery and mortar rounds, illuminating projectiles, pyrotechnics, bulk explosives, rockets, propellant, and regular and smoke grenades. According to EOD personnel, there are no records or information indicating any disposal of CB

agents, acids, solvents, or other hazardous or toxic substances in the EOD area (Environmental Science and Engineering 1983).

4.7.4 Potential for Releases/Known Releases

During the U.S. Army Environmental Hygiene Agency 1987 soils survey, sampling crews conducted a transect across EOD Area FST-011 collecting 10 samples at 40-foot intervals, each oriented to intersect as many craters as possible. The crew limited soil sampling to the uppermost 1 inch of soil due to the safety precautions associated with unexploded ordnance. The samples were analyzed for metals using total digestion procedure (total metals) and the EP TOX.

Metals analysis from the 1987 U.S. Army Environmental Hygiene Agency Survey of the samples collected at EOD Area FST-011 are presented below (Appendix 4.16). As written in that report, the analysis for total metals showed the existence of various levels of arsenic (1.98 to 21.4 ppm), barium (2.78 to 8.17 ppm), mercury (0.395 to 0.414 ppm), and lead (35.8 to 432.0 ppm) in all of the samples. These metals were also found in the background samples in approximately the same concentration. The report indicated that two samples collected from this area contained levels of total lead (432 ppm and 191 ppm) which significantly exceeded the lead concentrations in the background samples.

Other metals found in these samples were selenium to 0.787 ppm (1 of 9 samples), total chromium ranging from 3.69 to 4.35 ppm (3 of 9 samples), and cadmium ranging from 1.98 to 518.0 ppm (8 of 9 samples). The analysis for EP Tox metals failed to reveal the existence of any of these metals above the detection limit of the analysis, except for one sample. Sample 30 from the berm of the main crater (central crater) contained 0.43 milligrams per liter (mg/L) cadmium. This result is less than the 1.0 mg/L RCRA criteria for hazardous waste as outlined by 40 CFR 261.24. Therefore, these results failed to show that this area contains hazardous wastes (HWs) as defined by 40 CFR 261.24. The conclusions of the report were that although the metals exist in the soil, they are not leachable as defined by EP Tox. Thus, the report indicated that these metals were not mobile in the soil and did not pose a risk to human health or the environment.

4.7.5 Proposed Work and Sample Analyses

4.7.5.1 General

The following work is proposed for the Phase I investigation:

- 1) The soil sample data from April 1987 is submitted in Appendix 4.14.
- 2) A map will be prepared showing locations and depth of the samples.
- 3) Soil samples will be collected in the approximate location of the blast craters and analyzed according to GA EPD recommendations for pH, specific conductance, RCRA metals, and explosive residue.
- 4) The need for ground-water monitoring wells will be determined from data collected during the Phase I investigation and may be recommended for Phase II.

4.7.5.2 Field Sampling Plan

Surface soils in the blast craters will be sampled at five locations in EOD area FST-011 and analyzed for pH by EPA Methods 9040/9045, specific conductance by EPA Method 9050, RCRA metals by EPA Methods 6010 + 7470/7471 + 7060 + 7421 + 7740, and explosive residue by EPA Method 8350. One additional background sample will be collected and analyzed for the same parameters. One extra sample set and equipment blank for explosive residue will be collected for lab duplication/split analysis and QA/QC. Refer to Table 6.1 for sampling summary. Field sampling will follow procedures found in the QAPP (Attachment A) and the Field Sampling Approach (Section 6.0). The need for ground-water monitoring or additional sampling will be proposed and completed during Phase II.

4.8 The Current EOD Area (FST-012)

4.8.1 Site Description and History

The current EOD Area (FST-012) is located between the Artillery Impact Area and the Small Arms Impact Area south of the Canoochee River (see Figure 4.20) in the designated EOD area between B-9 and B-3, approximately 6 miles north of the cantonment area (Figure 4.27). The current EOD Area (FST-012) has been in operation from 1987 to the present. Disposal of unexploded ordnance is completed by thermal treatment methods. This area consists of blast craters occupying a total of approximately 3 acres.

4.8.2 Previous Investigations

None of the past soil investigation included the current EOD Area (FST-012). Consequently, no information is available for this unit.

4.8.3 Waste Characterization

The waste characterization of the EOD areas as indicated in the initial RFA (USEAH 1988) includes excess artillery powder bags, small arms rounds, artillery and mortar rounds, illuminating projectiles, pyrotechnics, bulk explosives, rockets, propellant, and regular and smoke grenades. More recent wastes found in the current EOD area, include unserviceable light antitank weapons (LAWs), dragons, and 2.75-inch rocket motors (U.S. Army Environmental Hygiene Agency 1987, U.S. Army Environmental Hygiene Agency 1988). According to EOD personnel, there are no records or information indicating any disposal of CB agents, acids, solvents, or other hazardous or toxic substances in the EOD area (Environmental Science and Engineering 1983).

4.8.4 Potential for Releases/Known Releases

None of the past soil investigations included the current EOD Area (FST-012). Consequently, no information is available to characterize the waste material at this unit. The potential for release would be similar to the other areas. No releases have been documented.

4.8.5 Proposed Work and Sample Analyses

4.8.5.1 General

The following work is proposed for the Phase I investigation at the current EOD Area (FST-012).

- 1) The blast area craters will be sampled according to GA EPD recommendations for pH, specific conductance, RCRA metals, and explosive residue.
- 2) A map showing sampling locations and depths will be prepared and submitted.
- 3) Soil samples will be collected in the approximate location of the blast craters (Figures 4.27A) and analyzed according to GA EPD recommendations for pH, specific conductance, RCRA metals, and explosive residue.
- 4) The need for ground-water monitoring wells will be determined from data collected during the Phase I investigation and may be recommended for Phase II.

4.8.5.2 Field Sampling Plan

Surface soils in the blast craters will be sampled at five sample locations in the current EOD area FST-012 and analyzed for pH by EPA Methods 9040/9045, specific conductance by EPA Method 9050, RCRA metals by EPA Methods 6010 + 7470/7471 + 7060 + 7421 + 7740, and explosive residue by EPA Method 8350. One additional background sample will be collected and analyzed for the same parameters. Refer to Table 6.1 for sampling summary. Field sampling will follow procedures found in the QAPP (Attachment A) and the Field Sampling Approach (Section 6.0). The need for ground-water monitoring or additional sampling will be proposed and completed during Phase II.

4.9 The Old Fire Training Pit (FST-014)

4.9.1 Site Description and History

The old fire training pit (FST-014) is located on the southwest boundary of the cantonment area across road FTS 90 from Zouck's Cemetery, behind the current facility engineering storage yard (Figure 4.28). During the 1940s to the 1950s, crash response crews used this area for fire fighting training exercises, burning waste oil and petroleum contaminated with water as fuel (USAEH, 1987). The site has been recently used for storage of leaves and pine needles collected from the cantonment area. During March 24 to 31, 1987, the northwest portion of the old fire training pit was actively burning or smoldering due to either spontaneous combustion or being set on fire. Currently, the site is an open grass field as seen on the November 1, 1990 site visit by Geraghty & Miller.

4.9.2 Previous Investigations

A previous investigation was completed in March 1987, Hazardous Waste Study No. 37-26-0127-88 Investigation of Soil Contamination by U.S. Army Environmental Hygiene Agency. The work was referenced in two subsequent reports: 1) 1988 Environmental Program Review No. 32-24-7038-89 by the U.S. Army Environmental Hygiene Agency, and 2) 1987 Evaluation of Solid Waste Management Units No. 37-26-1382-88 by the U.S. Army Environmental Hygiene Agency.

Four boreholes (BH5 to BH8) were drilled to 5-foot depths by the U.S. Army Environmental Hygiene Agency (Figure 4.29) to obtain soil samples. Eleven samples were collected from these four boreholes and submitted for analyses. The results from these analyses are presented in Appendix 4.14 and soil boring logs in Appendix 4.15.

4.9.3 Waste Characterization

The fire training area was used by the crash response crews for training exercises. Fires were ignited with waste oil and petroleum contaminated with water as fuel. The waste characterization of the old fire training pit includes waste oil, solvents, and waste fuels contaminated with water.

4.9.4 Potential for Releases/Known Releases

During the 1987 U.S. Army Environmental Hygiene Agency survey, 13 soil samples (including quality control) were collected from four boreholes and from the burn residue in the pit. The soil samples were submitted for analyses of metals using the total digestion procedures (total metals) and EP Tox. Additional samples were submitted for analyses of volatile organics (EPA Method 8240) and base-neutral extractable organics (EPA Method 8270). The complete analytical results by U.S. Army Environmental Hygiene Agency of the soil samples are included in Appendix 4.14.

The results of sample analyses indicated no significant contamination. A sample of the burn residue contained 505 ppm total lead, 25.7 ppm of total cadmium, and 5.9 ppm of total chromium. The lead concentration in this sample significantly exceeded the lead concentration of any of the background samples. Three soil samples contained levels of cadmium and chromium ranging from 1.95 to 4.99 ppm, and 7.17 to 11.9 ppm, respectively. However, the results as determined by the EP Tox test for lead, cadmium, and chromium plus the other metals revealed that none of the metals were above detection limits (Letter, U.S. Army Environmental Hygiene Agency, November 18, 1987). The results of the organic analysis indicated that no volatile organics or acid and base-neutral extractable organics were detected from samples collected in this area.

The soils in the area consist of fine sands and sandy soils which are well drained and exhibit an extremely low pH. Ground-water flow and hence migration pathways are inferred to follow the topography of the area (Figure 4.30), from south to north. The potential for migration of the fuels or waste oil to the shallow aquifer is high. The past investigations have not characterized the impact to the ground water.

FIGURE
4.30

4.9.5 Proposed Work and Sample Analyses

4.9.5.1 General

The following work is proposed for the Phase I investigation at the Old Fire Training Pit (FST-014):

- 1) A topographic survey was done in August 1990 by the COE. Well locations will be shown on the topographic map. This map will be submitted in the Phase I RFI report.
- 2) Four ground-water monitoring wells will be constructed at this site which meet all COE and GA EPD recommendations. One soil sample will be collected from each monitoring well boring and analyzed for pH, VOCs, total petroleum hydrocarbons (TPH), and RCRA metals.
- 3) The four new monitoring wells will be sampled and analyzed according to GA EPD recommendations for pH, VOCs, TPH, and RCRA metals.
- 4) One representative north-south and one east-west cross section of the four monitoring wells in the Old Fire Training Pit will be submitted in the final RFI report (Phase I).
- 5) One round of water-level data will be collected and used to determine ground-water flow direction. A potentiometric map of the site will be prepared and submitted. Ground-water flow rate will be determined in the Phase II investigation.
- 6) Soil sample data from April 1987 is submitted for GA EPD review in Appendix 4.14.

4.9.5.2 Soil Boring and Monitor-Well Installation Plan

Four ground-water monitoring wells (one upgradient and three downgradient), will be installed. These monitoring wells will be installed by drilling with a rig (hollow-stem auger

method). Proposed well placement is shown in Figure 4.30. The monitoring wells will be installed with a 10 foot screen to a depth of 5-8 feet into the saturated zone of the surficial sand aquifer in accordance with the Field Sampling Approach (Section 6.0). Well protection around each well will be installed to include concrete pads, protective casing, locking well covers, and protective posts at the corners of the well pads.

4.9.5.3 Field Sampling Plan

In accordance with GA EPD's recommendations, the four wells will be sampled once and analyzed for VOCs by EPA Method 8240, pH by EPA Methods 9040/9045, RCRA metals by EPA Methods 6010 + 7470/7471 + 7060 + 7421 + 7740, and TPH by EPA Method 8015. One equipment blank and one trip blank will be submitted for QA/QC analysis. One sample set will be submitted for lab duplication/split and rinsate analyses. Field measurements for specific conductivity and pH will be recorded for each well.

Soil samples will be collected every 2 feet during drilling, to the depth of the well. Soil samples will be collected from the ground surface to the water table. Each sample will be screened in the field with an organic vapor analyzer with a flame ionization detector (OVA-FID). The one sample that yields the highest reading or appears contaminated will be retained for analysis. If none of the samples appear to be contaminated, the sample above the water table will be retained for testing.

The soil sample will be analyzed in accordance with GA EPDs recommendations for VOCs by EPA Method 8240, pH by EPA Methods 9040/9045, RCRA metals by EPA Methods 6010 + 7470/7471 + 7060 + 7421 + 7740, and TPH by EPA Method 8015. One extra sample set of soil and ground water will be submitted for lab duplication/split analyses. One equipment blank will be submitted for QA/QC analysis, and one trip blank for soil and ground water. Refer to Table 6.1 for sampling summary. Field sampling will follow procedures found in the QAPP (Attachment A) and the Field Sampling Approach (Section 6.0). Additional wells, if needed, will be proposed in the Phase II investigation.

4.10 DRMO Hazardous Waste Storage Area (FST-017)

4.10.1 Site Description and History

The DRMO Hazardous Waste Storage Area (FST-017) is located in the cantonment area on the west side of Building 1152 (Figure 4.31A). The storage area dimensions were 25 feet wide by 50 feet long. According to the Environmental Program Review (U.S. Army Environmental Hygiene Agency, 1988), the storage area was neat, with most containers of waste in over pack containers and no evidence of any leaks or spills on the asphalt surface.

This area stored hazardous waste from 1985 until 1988. Hazardous waste is no longer stored at this site. The U.S. Army Environmental Hygiene Agency report noted that some previous labelling and packaging of hazardous waste has not conformed to all federal and DOT regulations (40 CFR 262.30, 40 CFR 262.32, 40 CFR 262.31, and 40 CFR 172). Also, sometimes the original manifest was prepared incorrectly.

4.10.2 Previous Investigations

No investigations have been conducted at the Hazardous Waste Storage Area (FST-017) to evaluate releases to the environment. Two reports on SWMUs at Fort Stewart generated as part of the initial RFA, mentioned the DRMO Hazardous Waste Storage Area: 1) 1988 Environmental Program Review No. 32-24-7038-89 by the U.S. Army Environmental Hygiene Agency, and 2) 1987 Evaluation of Solid Waste Management Units No. 37-26-1382-88 by the U.S. Army Environmental Hygiene Agency.

4.10.3 Waste Characterization

The waste characterization for the DRMO hazardous waste storage area includes lead-acid batteries which are palletized and covered, leaking drums of hazardous materials in over-pack containers, spill cleanup residue in over-pack containers, and drums of excess hazardous materials.

FIGURE
4.31A

4.10.4 Potential for Releases/Known Releases

Ground-water flow migration pathways are inferred to follow the topography (Figure 4.31B) from the northeast to southwest. No evidence of release is apparent according to documentation available. However, as indicated in the initial RFA report (No. 37-26-1382-88) the potential for a release to be carried to surrounding surface waters in an adjacent ditch is moderate.

4.10.5 Proposed Work and Sample Analyses

4.10.5.1 General

The following work is proposed for the Phase I investigation at the DRMO Hazardous Waste Storage Area (FST-017):

- 1) Soil samples shall be collected upgradient and downgradient of the former storage area.
- 2) Hazardous waste is no longer stored at this site, therefore a description of the current site conditions will be submitted in the Phase I RFI report.
- 3) As-built drawings with topography of the site are available and are submitted as Figure 4.31B.

4.10.5.2 Soil Boring and Monitor-Well Installation Plan

Four soil borings will be collected on the downgradient side of the former storage area. These soil borings will be installed using the hand-auger method. The soil borings will be installed to a depth of 2 feet into the saturated zone of the surficial sand aquifer in accordance with the Field Sampling Approach (Section 6.0).

4.10.5.3 Field Sampling Plan

Soil samples will be collected from every hand auger bucket during installation of the boring. Soil samples will be collected from the ground surface to the water table. Each sample

will be screened with an OVA-FID. The one sample that yields the highest reading or appears contaminated will be retained for analysis. If none of the samples appear to be contaminated, the sample above the water table will be retained for testing. In accordance with the GA EPD's recommendations, sample analysis will include VOCs by EPA Method 8240 and all TCLP constituents. One extra TCLP sample set will be submitted for matrix analysis. One trip blank will be submitted for QA/QC analysis. Refer to Table 6.1 for sampling summary. Field sampling will follow procedures found in the QAPP (Attachment A) and the Field Sampling Approach (Section 6.0). If a minimum groundwater detection system is warranted; this will be proposed in the Phase I RFI Report.

4.11 The Industrial Wastewater Treatment Plant (FST-018)

4.11.1 Site Description and History

The Industrial Wastewater Treatment Plan (IWTP) (FST-018) is located on the western portion of the cantonment area west of Building 4420 (Figure 4.32). The IWTP has been in operation since 1981. It consists of a pump station, bar screens, an 18-inch Parshall flume, three 25 foot x 100 foot sedimentation and oil separation basins with slotted pipe oil skimmers, a 5 million gallon (MG) flow equalization basin, four 107 foot x 328 foot sand filters, and a final 12-inch Parshall flume for measuring IWTP effluent flow (Figure 4.33). A small building adjacent to the influent structure contains lab and storage space. A schematic of the IWTP and plant design specifications are shown in Figure 4.34.

Wastewater dewatering from wash racks, grease racks, and maintenance areas flow from a lift station to three sedimentation basins, which have oil skimming systems. Solids settle in the sedimentation basins. Basins are drained when sufficient amount of solids have accumulated in the process of dewatering the sludge. The sludge that accumulates in the sludge holding tanks is periodically removed to the sewage treatment plant where it is pumped into the aerobic digester for treatment and dewatering. There is a 4000-gallon underground waste oil tank at this site that overflowed in 1989. The oil in the 4000-gallon storage tank is pumped out every one to two weeks to a tank truck and transferred to a 10,000-gallon storage tank. No previous history of the tank is known. This tank is not part of FST-025.

4.34

4.11.2 Previous Investigations

Three previous investigations were conducted at this site: 1) 1983 Environmental Science and Engineering Installation Assessment of Headquarters, 2) 1985 Wastewater Quality Engineering Consultation No. 32-62-0130-86 by United States Army Environmental Hygiene Agency, and 3) 1988 Environmental Program Review No. 32-24-7038-89 by the U.S. Army Environmental Hygiene Agency. The first two reports are referenced in the initial RFA, U.S. Army Environmental Hygiene Agency 1987 Evaluation of Solid Waste Management Units, No. 37-26-1382-88. The industrial wastewater also includes the discharge from the Central Energy Wood Fired Boiler stack scrubber. This is predominantly carbon, ash, and by products of combustion.

4.11.3 Waste Characterization

Wastewater from the wash racks, grease racks, and maintenance areas is the waste introduced to the treatment plant. A general characterization of the IWTP Sludge Tanks includes oily sludge, methylene chloride degreaser and crankcase oil.

An analysis of the sludge samples was completed during the 1985 U.S. Army Environmental Hygiene Agency survey to determine if the sludge or wastewater would be classified as hazardous wastes. The analyses were performed for flashpoint (ignitable waste), PCB content, EP Toxicity Metals and Oily Waste Extraction Procedure. The results of those analyses from 1985 U.S. Army Environmental Hygiene Agency are provided in Appendices 4.16 through 4.22.

The results of the analysis reported the flashpoint of all samples was greater than 140°F; therefore, the wastes were not considered ignitable. In all cases, the PCB concentrations were less than the detectable limit of 7.0 ppm. The metals concentrations determined by the extraction procedures (Methods 1310 and 1330) were well below the maximum concentration at which the waste is characterized hazardous by EP toxicity. Only cadmium was found above detectable limits. A cadmium concentration of 0.14 mg/L was found in the sludge samples which is well below the maximum concentration of 1.0 mg/L.

Samples of the wastewater and sludge from the 1985 United States Army Environmental Hygiene Agency study were also analyzed for total metals. Analysis of the samples was

performed by the U.S. Army Environmental Hygiene Agency following the maximum concentration of contaminants for characteristic of EP Toxicity (Table 1, 40 CFR 261.24). Results from these analyses are found in Appendices 4.16 through 4.22. United States Army Environmental Hygiene Agency defined a level of concern as 100 times the maximum concentrations of the EP Toxicity Test. Although all the metals concentrations were well below the level of concern, there were concentrations significantly above the level of detection for chromium and cadmium in the wastewater, and of barium, chromium, cadmium, and lead in the sludge. These concentrations of metals indicate that materials containing these metals are entering the IWTP system.

Sampling for priority pollutants organics was performed in 1985 using USEPA sampling procedures. However, no trip blanks were analyzed. Due to interference by the high hydrocarbon content of the wastewater and sludge samples, the detection limits were elevated 10 to 100 times above the normal detection limits for analyses of the base/neutral extractable organics, the acid extractables, and the pesticides/PCBs. Because of this, these analyses provide very little meaningful information.

The analytical results from 1985 U.S. Army Environmental Hygiene Agency study for volatile organics show that significant concentrations of 1,1,1, trichloroethane; (i.e., 160-340 ug/g) were present in the wastewater and sludge. Those concentrations indicated that 1,1,1, trichloroethane (which is used as a degreasing solvent) was present in the IWTP system.

4.11.4 Potential for Releases/Known Releases

Since the IWTP is not designed to handle 1,1,1, trichloroethane; the potential for release by way of treated wastewater to the surface water is high. The potential for release to the ground water and soil as indicated in the initial RFA is low. Ground-water flow and hence migration pathways are inferred to follow the topography.

The waste oil tank on the IWTP site has not been previously investigated. In 1989, the underground waste oil tank overflowed (due to a design fault in the skimmer), therefore, potential for release to the soil is high near the tank.

4.11.5 Proposed Work and Sample Analyses

4.11.5.1 General

The following work is proposed for the Phase I investigation at the Industrial Wastewater Treatment Plant (FST-018):

- 1) The sampling and analysis conducted in 1985 is included in Appendices 4.16 through 4.22.
- 2) The sludge will be resampled and tested for the presence of 1,1,1-trichloroethane, and other VOCs by EPA Method 8240, all TCLP constituents, pH by EPA Methods 9040 and 9045, specific conductance by EPA Method 9050, and pesticides and PCBs by EPA Method 8080.
- 3) A detailed description of the sludge tanks and the rest of the site will be submitted to GA EPD.
- 4) There is also an underground waste oil tank located near the sludge tank that overflowed in 1989. Soil samples will be taken next to the tank, on the downgradient side, to a depth equal to the bottom of the tank. The samples will be analyzed according to GA EPD recommendations for VOCs (EPA Method 8240), TPH (EPA Method 8015), specific conductance by EPA Method 9050, and RCRA metals (EPA Methods 6010 + 7470/7471 + 7060 + 7421 + 7740).
- 5) The equalization basin influent and effluent wastewater will be sampled per GA EPD recommendations for VOCs, pH, RCRA metals, pesticides, and PCBs.
- 6) Three water and three sediment samples will be collected near the influent pipe of the equalization basin. Water and sediment samples will be collected at four separate locations around the equalization basin. Sediment from the equalization basin will be sampled according to GA EPD recommendations for RCRA metals, VOCs, pH, pesticides, and PCBs. Water samples will be analyzed for RCRA metals, VOCs, pH, pesticides and PCBs.

- 7) The sludge and/or sediment from the sand filters will be sampled per GA EPD recommendations for all TCLP constituents, VOCs, pH, pesticides, and PCBs.

4.11.5.2 Soil Borings Installation Plan

In accordance with GA EPD's recommendations, four soil borings will be taken next to the tank, on the downgradient side. Soil borings will be installed using the hand-auger method. The soil borings will be installed to a depth of the tank in accordance with the Field Sampling Approach (Section 6.0). OVA-PID or OVA-FID readings will be taken at two-foot intervals. Field sampling will follow procedures found in the QAPP (Attachment A) and the Field Sampling Approach (Section 6.0).

4.11.5.3 Field Sampling Plan

Soil samples will be collected from every hand auger bucket during installation of the boring. Soil samples will be collected from the ground surface to the water table. Each sample will be screened in the field with an OVA-FID. The one sample that yields the highest reading or appears contaminated will be retained for analysis. If none of the samples appear to be contaminated, the first sample above the water table will be retained for testing. The soil sample will be analyzed for RCRA metals (Methods 6010 + 7470/7471 + 7060 + 7421 + 7740), VOCs (Method 8240), and TPH (EPA Method 8015).

The sludge will be resampled and tested. The sludge will be analyzed for all TCLP constituents, VOCs (EPA Method 8240), pH (EPA Methods 9040/9045), and pesticides and PCBs (EPA Method 8080). One extra TCLP sample will be submitted for matrix analysis. One equipment blank will be submitted for QA/QC analysis. One extra sample set will be submitted for lab duplication/split analyses resulting in three samples to be analyzed.

One equalization basin influent and effluent wastewater sample will be collected and analyzed for VOCs by EPA Method 8240, pH by EPA Method 9040/9045, RCRA metals by EPA Methods 6010 + 7470/7471 + 7060 + 7421 + 7740, pesticides and PCBs by EPA Method 8080.

One equipment blank will be submitted for QA/QC analysis. One extra sample set will be submitted for lab duplication/split analyses.

Three water and three sediment samples from near the influent pipe of the equalization basin and four water and four sediment samples from select areas within the equalization basin will be collected. The water will be analyzed for RCRA metals by EPA Methods 6010 + 7470/7471 + 7060 + 7421 + 7740, VOCs by EPA Method 8240, pH by EPA Method 9040/9045 and pesticides and PCBs by EPA Methods 8080. The sediment will be collected and analyzed for VOCs by EPA Method 8240, all TCLP constituents, pH by EPA Methods 9040/9045 and pesticides and PCBs by EPA Method 8080. One sludge/sediment sample will be collected from the sand filters and analyzed for all TCLP constituents, VOCs by EPA Method 8240, pH by EPA Method 9040/9045, and pesticides and PCBs by EPA Method 8080. One extra TCLP sample will be submitted for matrix analysis. Refer to Table 6.1 for sampling summary. Field sampling will follow procedures found in the QAPP (Attachment A) and the Field Sampling Approach (Section 6.0). If needed, a minimum groundwater detection system will be proposed in the Phase I RFI Report.

4.12 The Old Sludge Drying Beds (FST-019)

4.12.1 Site Description and History

The old sludge drying beds are located in the north central portion of the cantonment area in the P5000 block next to the old sewage treatment plant (Figure 4.35). Sludge from the domestic wastewater treatment plant was dewatered at this site from the 1960s to 1985. The old sludge drying beds were closed before a formal closure was required. According to Mr. Thomas Houston (personal communication 1990), these beds were removed and backfilled in 1989. The area currently has a good grass cover.

4.12.2 Previous Investigations

No previous investigations have been conducted at the old sludge drying beds. They are included as a SWMU in the 1987 initial RFA, U.S. Army Environmental Hygiene Agency Evaluation of Solid Waste Management Units publication No. 37-26-1382-88.

4.12.3 Waste Characterization

The waste characterization of the old sludge drying beds includes sludge from the domestic wastewater treatment plant incorporated in a sand media. There is a potential for some contaminants to concentrate in the media but no analysis is available that characterizes the waste.

4.12.4 Potential for Releases/Known Releases

No past sampling of soil or ground water has been conducted at this site to evaluate a release. The potential for release as evaluated in the initial RFA, was low.

4.12.5 Proposed Work and Sample Analyses

No previous investigations have been conducted at the old sludge drying beds. To facilitate an evaluation of this site, a description of the current site conditions and the abandonment procedures followed during closure will be submitted to the state for review. Recommendations for Phase II work will be included in the Phase I RFI Report.

4.13 The Wright Air Field Sewage Disposal Beds (Land Spray Application and Lagoon - FST-020).

4.13.1 Site Description and History

The Wright Air Field sewage disposal bed land spray application and lagoon is located east of the cantonment area, one-half mile south of Wright Army Airfield (Figure 4.36). According to 1989 Georgia Department of Natural Resources report, the lagoon and land application system has been active for forty years (1950s to present). Approximately 3000 gallons per day of wastewater is discharged to a series of two, lined, biological, oxidation lagoons followed by a spray irrigation field. The primary lagoon was aerated with a floating aerator (U.S. Army Environmental Hygiene Agency 1988). The estimated capacity of the plant is 24,500 gpd. The facility operates under an NPDES permit which requires monitoring of seven monitoring wells on a routine basis.

SAVANNAH, GEORGIA

RCRA FACILITY INVESTIGATION
WRIGHT AIR FIELD SEWAGE DISPOSAL BEDS LOCATION MAP FST-020
FORT STEWART
GEORGIA

FIGURE
4.36

4.13.2 Previous Investigations

Two previous investigations were conducted at Fort Stewart which included an evaluation of this site: 1) 1988 Environmental Program Review No. 32-24-7038-89 by the U.S. Army Environmental Hygiene Agency and, 2) 1983 Installation Assessment of Headquarters by Environmental Science and Engineering. Two additional reports were prepared which referenced these investigations: 1) 1987 Evaluation of Solid Waste Management Units by U.S. Army Environmental Hygiene Agency, No. 37-26-1382-88 and, 2) 1989 Environmental Priorities Initiative Preliminary Assessment of Fort Stewart by Georgia Department of Natural Resources.

Effluent monitoring has been conducted on a monthly basis at the Wright Air Field Sewage Disposal Beds. The land application permit summary is listed in Table 4.4. Drilling logs (Appendix 4.25) provided by the COE (1979) record the boring of four holes (CS-3, A-21, A-22, A-23) in May 1976 and seven holes (OW-1 through OW-7) in April 1979 (Figure 4.37). No other information was provided with these drilling logs. Wells were installed in Borings OW-1 through OW-7.

4.13.3 Waste Characterization

The waste characterization of the Wright Airfield Sewage Beds is treated domestic wastewater.

4.13.4 Potential for Releases/Known Releases

No evidence of release is known or has been documented. The potential for release of wastewater treatment effluent to the surface water exists. The potential for release to soil or ground water is low because of the solids handling practices.

Table 4.4 NPDES Permit Effluent Limitations*, Sewage Treatment Plant (FST-020).

Parameter†	8/14/75 through 6/30/77		7/1/77 through 8/14/80

† MGD = million gallons per day.

BOD = biochemical oxygen demand.

ml = milliliters.

Source: Environmental Science and Engineering 1983

4.13.5 Proposed Work and Sample Analyses

4.13.5.1 General

The following work is proposed for the Phase I Investigation at the Wright Air Field Sewage Disposal Beds:

- 1) FST-020 is a permitted NPDES facility that requires routine sampling of seven monitoring wells. The well construction logs for these wells are included in Appendix 4.23.
- 2) The current conditions of the site and the status of the NPDES permit will be described in the Phase I Report. Ground-water sampling parameters and sample collection frequency outlined in the NPDES permit will be investigated and included into the final plan, if available.
- 3) All existing ground-water data for the monitoring well system will be investigated and submitted in the final plan, if available.
- 4) An investigation into the loading rate for priority pollutants on the spray field will be conducted. If the information is available, it will be submitted in the Phase I RFI report.
- 5) An expanded summary of the two previous investigations will be included in the Phase I RFI report, if more information is available.

4.14 The Radiator Shop (FST-024)

4.14.1 Site Description and History

The (new) radiator shop (FST-024A) is located inside building 1070 in the southern portion of the cantonment area (Figure 4.38). The old radiator shop is located inside building 1056 (FST-024B) in the southern portion of the cantonment area. The work area for the new radiator shop is approximately 20 feet x 20 feet. The new shop has been in operation since 1980.

RCRA FACILITY INVESTIGATION
RADIATOR SHOP FST-024A AND FST-024B¹
FORT STEWART

GEORGIA

FIGURE
4.38

Radiators are repaired by descaling the radiator and soaking it in an aqueous solution of sodium hydroxide. The next step is to encapsulate this caustic waste solution by mixing it with concrete and sodium silicate and disposing it in the landfill. The radiator is then leak tested using a fluorescein dye and painted in a wet curtain spray paint booth. According to the COE (1990), encapsulating is not performed any longer.

4.14.2 Previous Investigations

Two previous investigations conducted at Fort Stewart mentioned this site: 1) 1983 Installation Assessment of Headquarters (Environmental Science and Engineering), and, 2) 1987 Evaluation of Solid Waste Management Units No. 37-26-1382-88 (U.S. Army Environmental Hygiene Agency). No previous sampling was completed at this site.

4.14.3 Waste Characterization

Waste generated at the radiator shop is related to the maintenance and cleaning of radiators. The waste characterization includes caustic waste cleaning solution, sodium hydroxide, water-based fluorescein dye solution, and spent recirculation water from the wet curtain spray paint booth.

4.14.4 Potential for Releases/Known Releases

According to the Environmental Science & Engineering report (1983), wastes were discharged to a drain field located adjacent to Building 1070 from 1980 to late 1981 from the new radiator shop (FST-024A). The Environmental Science & Engineering report estimated that only about one pound of lead was discharged to the drain field during this two-year period. According to the Environmental Science & Engineering report (1983), wet curtain recirculation wastewater discharge is routed to the IWTP. Since late 1981, the caustic waste cleaning solution has been handled as a hazardous waste.

The fluorescein dye solution and paint booth recirculation water, which is non-hazardous, has been conveyed onto the ground outside Building 1070 near the drainfield, via a pipeline (Environmental Science and Engineering 1983). The initial RFA indicated that the exposure potential from a release at this unit is low.

The paint booth is located in building 1056 (FST-024B). The floor drain in Building 1056 is not relevant to the radiator shop in Building 1070. The drain in building 1056 has been connected with the industrial wastewater pipe (located across the road), for disposal at the IWTP. Therefore, discharge is no longer routed to the ditch. The ditch near building 1056 is not associated with the radiator shop in building 1070.

4.14.5 Proposed Work and Sample Analyses

4.14.5.1 General

The following work is proposed for the Phase I investigation at the Waste Oil Tanks (FST-025):

- 1) One sample of the "sludge" shall be collected and analyzed according to GA EPD recommendations for all TCLP constituents, VOCs, and pH (Figure 4.38A).
- 2) Sediment samples will be collected from the former drain field adjacent to building 1070 (Figure 4.38A) and analyzed according to GA EPD recommendations for all TCLP constituents.
- 3) DEH installed a pipe under the road that connects the drain pipe in building 1056 to the industrial pipe located across the road. If drawings are available of this improvement, they will be submitted in the Phase I RFI report.
- 4) A description of the current site conditions and DEH plans will be submitted to the state for review.
- 5) The ditch will not be sampled because the drain no longer discharges to the ditch.
- 6) The date the encapsulating practice ceased will be investigated and included in the Phase I RFI report, if available.

GEORGIA

FIGURE
4.38A

- 7) A detailed description of the descaling process and drainage schematics for the paint booth will be provided in the Phase I RFI report, if available.

4.14.5.2 Field Sampling Plan

The radiator "sludge" will be sampled once and analyzed for all TCLP constituents, VOCs by EPA Method 8240, and pH by EPA Methods 9040/9045, in accordance with GA EPD's recommendations. One extra TCLP sample of the sludge will be collected for matrix analysis.

Three sediment samples will be collected from the former drain field. Sediment samples will be collected from the ground surface to the water table. Each sample will be screened with an OVA-FID. The one sample that yields the highest reading or appears contaminated will be retained for analysis. If none of the samples appear to be contaminated, the first sample above the water table will be retained for testing.

The three sediment samples will be analyzed for all TCLP constituents. One extra TCLP sediment sample will be submitted for matrix analysis. Refer to Table 6.1 for sampling summary. Field sampling will follow procedures found in the QAPP (Attachment A) and the Field Sampling Approach (Section 6.0).

The GA EPD recommendations included testing the encapsulating concrete and sampling the ditch near the former discharge area. However, since the encapsulating procedure is no longer in operation and the drain now discharges into the IWTP, sampling will not be performed.

4.15 The 86 Waste Oil Tanks (FST-025)

4.15.1 Site Description and History

Eighty-six waste oil tanks are located at various areas within the cantonment area as shown in Plate 3 and as listed in Table 4.5. The waste oil tanks for the most part are situated in motor pools and have been in operation over a time period from 1950 to the present. Most of the tanks are underground and are constructed of concrete, fiberglass, or steel. However, some of the tanks are aboveground with a containment wall around them. The capacity of the storage tanks varies from 150 to 11,000 gallons.

Table 4.5 Master List of Waste Oil Tanks (FST-025).

275

Tank No.	Building No.	Capacity (gallons)	Construction Material	Installation Date	Ground Cover
1	1841	1000	Fiberglass	1982	Concrete
4	1840	2500	Fiberglass	1982	Concrete
4A	1840	1000	Steel	1982	Dirt w/ Cement Pad

SCALE: 1" = 500'

4.15.2 Previous Investigations

Fort Stewart has conducted several investigations over the past few years to inventory all underground storage tanks (USTs) and to perform tank, and associated pipeline tightness tests. The waste oil tanks were included in these investigations.

The results of these investigations have been referenced in several reports: 1) 1987 Evaluation of Solid Waste Management Units No. 37-26-1382-88. (U.S. Army Environmental Hygiene Agency), 2) 1988 Underground Tank and Pipeline Test Certification Report by Tracer Research Corporation for DEH Environmental Office, and 3) 1988 Environmental Program Review (U.S. Army Environmental Hygiene Agency). The waste oil was determined to be non-hazardous and to meet specifications in 40 CFR 266.40 from the past test results that the Fort Stewart Environmental Office has scheduled (U.S. Army Environmental Hygiene Agency, 1987).

4.15.3 Waste Characteristics

The product disposed of in the waste oil tanks is waste product associated with maintenance in the motor pools. A characterization of the product in the waste oil tanks would include a mixture of waste oil, non-hazardous used standard type II solvent, used antifreeze, and used hydraulic fluid. According to the initial RFA developed by U.S. Army Environmental Hygiene Agency (1987), past test results of waste oil at Fort Stewart meets the specifications in 40 CFR 266.40.

4.15.4 Potential for Releases/Known Releases

Evidence of releases from the waste oil tanks have not been documented. However, the potential for a release to the environment is high in the event of tank failure. If a UST leaked, the waste oil could migrate to the shallow aquifer and subsurface soils. Surface water, ground water, or soils would be threatened if an aboveground tank leaked and the secondary containment failed.

4.15.5 Proposed Work and Sample Analyses

4.15.5.1 General

The following work is proposed for the Phase I investigation for the Waste Oil Tanks (FST-025):

- 1) Most recent information from Fort Stewart indicates that there are approximately 86 underground waste oil tanks on the installation. A list of tanks with building numbers is provided as Table 4.5. After the "walk-over" investigation, Table 4.5 will be updated to include questionable data.
- 2) A map that clearly shows all waste oil tanks at Fort Stewart has been constructed. The full size map (Plate 3) will be updated to show which tanks are aboveground.
- 3) Each tank will be given a "walk-over" investigation. The purpose will be to verify location and to note any signs of contamination. The following information shall be provided for each tank: type of tank, ground cover at tank, building number, number on tank, if any. The condition of the concrete will be checked.
- 4) Soil samples will be collected to the depth of the water table or 5 feet below the bottom of the tank at USTs not entirely covered by concrete, or at USTs with concrete that is cracked or in poor condition. If the tank bottom is within the water table, a ground-water sample will be collected and analyzed. During the soil sampling, the orientation of these tanks will be determined.
- 5) Soil sampling at aboveground tanks will be done during Phase II, if needed.
- 6) Samples shall be tested according to GA EPD recommendations for RCRA metals, pH, and TPH.
- 7) Tank tightness tests (Tracer method) will be performed on USTs entirely covered by concrete in good condition during the Phase I field investigation. During the tightness tests, the orientation of these tanks will be determined.

4.15.5.2 Soil Boring and Monitor-Well Installation Plan

The orientation of the USTs (that soil samples will be collected from) will be determined by carefully by boring by hand auger to find the edge of the tank. Once the edge of the tank is identified, the test borings may be initiated. The soil borings will be installed to a depth to the water table or 5 feet below the bottom of the tank (if possible with a hand auger) at eleven underground waste oil tanks. Soil samples will be collected from every hand auger bucket during installation of the boring. Soil samples will be collected from the ground surface to the water table. Each sample will be screened with an OVA-FID. The one sample that yields the highest reading or appears contaminated will be retained for analysis. If none of the samples appear to be contaminated, the first sample above the water table will be retained for testing.

4.15.5.3 Field Sampling Plan

Eleven tank sites have a dirt cover over the USTs. Therefore, the eleven tank areas to collect soil and possibly ground-water samples are: 4A, 56, 64, 64A, 67, 70, 94A, 100A, 100B, 214, and 215. One soil sample will be collected at each tank and analyzed for pH by EPA Methods 9040/9045, TPH by EPA Method 8015, and all TCLP constituents. One extra duplication/split sample set will be collected. One equipment blank will be submitted for QA/QC analysis. One extra TCLP sample will be submitted for matrix analysis. If ground water is encountered prior to reaching the bottom of a UST, then a ground-water sample for that UST will be submitted and analyzed for VOCs by EPA Method 8240, TPH by EPA Method 8015, RCRA metals by EPA Methods 6010 + 7470/7471 + 7060 + 7421 + 7740 and pH by EPA Methods 9040/9045. Refer to Table 6.1 for sampling summary. Field sampling will follow procedures found in the QAPP (Attachment A) and the Field Sampling Approach (Section 6.0). Recommendations for any further sampling or monitoring wells will be included in the Phase I Report.

4.16 The 724th Tanker Purging Station (FST-026)

4.16.1 Site Description and History

The 724th Tanker Purging Station is located on the western portion of the cantonment area near the fuel truck parking lot (Figure 4.39). The Purging Station is an area where tanker trailers that carry JP-4 Jet Fuel, #2 Fuel Oil and Mogas are routinely cleaned. This area consists of an

underground waste oil tank and an aboveground storage tank that receive water liquid after phase separation.

4.16.2 Previous Investigations

No previous investigations have been conducted in this area. The only report that briefly mentions the 724th Purging Station is 1989 GA EPD RFA Report entitled "Environmental Priorities Initiative Preliminary Assessment of Fort Stewart, Georgia.

4.16.3 Waste Characterization

The waste characterization for the 724th Tanker Purging Station includes waste liquids from the purging of the tanker trailer. These waste liquids contain assorted petroleum hydrocarbons to include JP-4, #2 Fuel Oil and Mogas.

4.16.4 Potential for Releases/Known Releases

No releases have been reported or documented from this area. However, the potential for spillage, and hence release to the soils around the tanks is high, and the release from the underground tank through failure of the tank is high.

4.16.5 Proposed Work and Sample Analyses

4.16.5.1 General

The following work is proposed for the Phase I investigation at the 724th Tanker Purging Station (FST-026):

- 1) Soil samples will be collected and analyzed according to GA EPD recommendations and results submitted for review. The samples will be collected on the upgradient and downgradient side of the purging area. Samples will be collected from the ground surface to a depth equal to approximately 1 foot into the saturated zone.

- 2) An investigation will be performed to determine if tank integrity tests have been performed. If the tests are available, they will be included in the Phase I RFI report.
- 3) The waste oil UST is associated with FST-025.
- 4) The need for ground-water monitoring wells will be determined from data collected during the Phase I investigation and may be recommended for Phase II.

4.16.5.2 Soil Boring and Monitor-Well Installation Plan

Four soil borings (one upgradient and three downgradient) will be installed. Four sets of soil samples will be collected from the ground surface to the water table. Soil samples will be collected from every hand auger bucket during installation of the boring. Each sample will be screened in the field with an OVA-FID. The one sample that yields the highest reading or appears contaminated will be retained for analysis. If none of the samples appear to be contaminated, the first sample above the water table will be retained for testing. The soil borings will be installed by using the hand-auger method in accordance with the Field Sampling Approach (Section 6.0).

4.16.5.3 Field Sampling Plan

The soil samples will be submitted for analysis of TPH by EPA Method 8015, VOCs by EPA Method 8240, all TCLP constituents, and pH by EPA Methods 9040/9045. An additional sample set will be included for duplication/splits. One equipment blank and one trip blank will be submitted for QA/QC analysis. One extra TCLP sample will be submitted for matrix analysis. Refer to Table 6.1 for sampling summary. Field sampling will follow procedures found in the QAPP (Attachment A) and the Field Sampling Approach (Section 6.0). Recommendations for any further sampling or monitoring wells will be included in the Phase I Report.

4.17 The Motor Pools (include wash racks, grease racks, and steam racks - FST-027).

4.17.1 Site Description and History

The motor pools and their associations, located throughout the cantonment area, are shown on Plate 4 and listed in Table 4.6. Wash racks, steam racks, grease racks, and oil/water separators are found at most motor pools. Many of the USTs (FST-025) are also located at the motor pools. The specific times of operations of these motor pools are unknown but assumed to be from the 1950's to the present.

4.17.2 Previous Investigations

Two previous investigations conducted at Fort Stewart mentioned the motor pool wash racks: 1) 1983 Installation Assessment of Headquarters (Environmental Science and Engineering) and 2) 1989 Environmental Priorities Initiative and Preliminary Assessment of Fort Stewart, Georgia (Georgia Department of Natural Resources).

4.17.3 Waste Characterization

The waste characterization for the motor pools includes waste oil, antifreeze, petroleum products, and possibly solvents.

4.17.4 Potential for Release/Known Releases

Wash racks and oil/water separators were installed in the mid-1970s. In consequence, the separator effluent lines were directed to the storm drainage system. Prior to the installation of the separators, the wash rack wastewater was discharged untreated to the storm drainage system. As of 1980, all but 20 separators were connected to the sanitary sewer. The remaining 20 were affiliated with the Georgia Army National Guard (GARNG), and discharge under the NPDES Permit No. GA0027685.

By the summer of 1982, all but three of the wash rack separators were connected to the new Industrial Wastewater Treatment Plant (IWTP). These three wash racks, located in the DIO and DEH maintenance areas, are monitored closely. During the 1983 onsite investigation, the

Note: See Plate 4 for locations.

effluent pipe from the oil/water separator for the wash rack near Building 1060 was broken. Consequently, wastewater exited through a hole in the side of the pipe and entered an open drainage ditch, rather than flowing through the pipe to the IWTP. Since this report, the pipe has been fixed. The potential for release to soils at all motor pools is high.

4.17.5 Proposed Work And Sample Analyses

4.17.5.1 General

The following work is proposed for the Phase I investigation for the Motor Pools (FST-027):

- 1) A complete inventory and description of the conditions at each motor pool will be prepared for submittal of the State's review. Plate 4 will be updated to show names and boundaries of each motor pool.
- 2) A location map (with specific motor pool and effluent line discharges identified) will be prepared for each motor pool for the Phase I RFI report.
- 3) Process schematics drawings for the three separators not hooked up to the industrial wastewater treatment plant will be provided in the Phase I RFI report, if available.
- 4) Soil samples will be collected from the drainage ditch near building 1060, where wastewater from the broken separator effluent line was discharging.

4.17.5.2 Soil Boring and Monitoring Well Installation Plan

One upgradient and two downgradient soil samples will be collected from the drainage ditch where wastewater from the broken separator effluent line was discharging. The samples will be collected to a depth of one foot below ground surface. Soil samples will be collected from every hand auger bucket during installation of the boring. Each sample will be screened in the field with an OVA-FID. The one sample that yields the highest reading or appears contaminated will be retained for analysis. If none of the samples appear to be contaminated, the last sample will be retained for testing. The borings will be installed in accordance with the Field Sampling Approach (Section 6.0).

4.17.5.3 Field Sampling Plan

In accordance with GA EPD's recommendations, the soil sample collected from each boring will be submitted for analyses of VOCs by EPA Method 8240, all TCLP constituents, TPH by EPA Method 8015, and pH by EPA Methods 9040/9045. Refer to Table 6.1 for sampling summary. Field sampling will follow procedures found in the QAPP (Attachment A) and the Field Sampling Approach (Section 6.0).

4.18 The 724th Battery Shop (FST-028)

4.18.1 Site Description and History

The 724th battery shop is located on the western portion of the cantonment area, northeast of the IWTP, behind building 1720 (Figure 4.40). To the best of our knowledge, this facility is an open air cage where batteries are filled, charged, and neutralized. The storage area for spent lead-acid batteries is on concrete. A leachate trail was noted across the parking lot to bare soil (Georgia Department of Natural Resources 1989). Recently the building has been enlarged and the concrete foundation repaired.

Prior to 1981, spent batteries were drained prior to being transported to the DPDO storage yard. Approximately 200 to 400 liters per week of acid was drained from the batteries into a lead-lined vat. Attempts to neutralize the acid by adding soda ash to the vat were unsuccessful (Environmental Science and Engineering 1983). This "neutralized" solution was then discharged into the storm drain system. Currently spent batteries are transferred without draining to the DPDO storage yard prior to sale to salvage contractors. Repairs were made to this system in 1990 and the old limestone rock used to neutralize the acid was disposed of as a hazardous waste.

4.18.2 Previous Investigations

The previous investigations concerning this site were mentioned in three previous reports: 1) 1983 Installation Assessment of Headquarters (Environmental Science and Engineering), 2) 1989 RCRA Facility Assessment Report (Georgia Department of Natural Resources), and 3) 1988 Environmental Program Review No. 32-24-7038-89 (U.S. Army Environmental Hygiene Agency).

U.S. ARMY ENGINEER DISTRICT, SAVANNAH
CORPS OF ENGINEERS
SAVANNAH, GEORGIA

RCRA FACILITY INVESTIGATION
BATTERY SHOP LOCATION MAP FST-028
FORT STEWART

GEORGIA

FIGURE
4.40

The Battery Shop has had two rounds of sampling completed at this location in 1989. One round was taken at the request of GA EPD at the edge of the motor pool (1 sample, 1 background). Additionally, the limestone rock used to neutralize the acid was tested prior to disposal as a hazardous waste. A sample was taken for Hazardous Waste characterization, and the results showed approximately 3600 ppm Lead by EP Toxicity Method.

4.18.3 Waste Characterization

The battery shop is an area where batteries are serviced and charged. The waste generated includes sulfuric acid from batteries and "neutralized" (soda ash) battery solutions that are associated with maintenance.

4.18.4 Potential for Releases/Known Releases

Prior to 1981, batteries were drained prior to sale to salvaging contractors. Evidence of spillage by deterioration of the concrete in the parking lot downgradient of the facility (U.S. Army Environmental Hygiene Agency 1988), and a dissolved portion of the concrete with a leachate trail across the parking lot to bare soil is evident at the battery shop (Georgia Department of Natural Resources 1989). It is estimated that about 2 pounds of lead was discharged per year when the hazardous neutralized battery acid was discharged to the storm drainage system prior to 1981 (Environmental Science and Engineering 1983). The potential for release to the soil and possibly the ground water is high.

4.18.5 Proposed Work and Sample Analyses

4.18.5.1 General

The following work is proposed for the Phase I Investigation for the Battery Shop (FST-028):

- 1) A complete description on the current site conditions will be prepared and submitted for review as part of the Phase I investigation.

- 2) The results of the 1989 soil sample analysis are included in Appendix 4.26.
- 3) Four soil samples (one upgradient of the battery shop and three at the areas described as having been screened) will be collected and analyzed for all TCLP constituents, TPH, and pH. The samples will be collected as close to the designated areas as possible (Figure 4.40A). It is possible that new buildings or pavement may cover these areas.
- 4) The need for ground-water monitoring wells will be determined from data collected during the Phase I investigation and may be recommended for Phase II.

4.18.5.2 Soil Boring Installation Plan

One soil sample will be collected upgradient of the battery shop in addition to one soil sample at each of the three areas described as having been screened. All soil samples will be installed to a depth of one foot into the water table. Soil samples will be collected from every hand auger bucket during installation of the boring. Soil samples will be collected from the ground surface to the water table. Each sample will be screened in the field with an OVA-FID. The one sample that yields the highest reading or appears contaminated will be retained for analysis. If none of the samples appear to be contaminated, the first sample above the water table will be retained for testing. The borings will be installed in accordance with the Field Sampling Approach (Section 6.0).

4.18.5.3 Field Sampling Plan

In accordance with GA EPD's recommendations, the soil sample collected from each boring will be submitted for analyses of all TCLP constituents, TPH by EPA Method 8015 and pH by EPA Methods 9040/9045. One extra TCLP sample will be submitted for matrix analysis. Refer to Table 6.1 for sampling summary. Field sampling will follow procedures found in the QAPP (Attachment A) and the Field Sampling Approach (Section 6.0).

4.19 The Evans Army Heliport POL Storage Facility (FST-029)

4.19.1 Site Description and History

The Evans Army Heliport POL Storage Facility is located approximately five miles northeast of the cantonment area, at the junction of State Road 144 and Fort Stewart 54 near the Evans Army Heliport. This area consists of two above-ground 250,000-gallon diesel tanks surrounded by a 5-foot high earth dike (covered by an asphalt layer) (Figure 4.41). The facility has been in operation at least since 1967 (COE 1967).

4.19.2 Previous Investigations

Investigations at this site were mentioned in two previous reports: 1) 1983 Installation Assessment Report (Environmental Science and Engineering), and 2) 1989 GA EPD RFA report, Environmental Priorities Initiative Preliminary Assessment of Fort Stewart, Georgia (Georgia Department of Natural Resources).

4.19.3 Waste Characterization

The waste at the Evans Army POL Storage Facility are related to the two diesel tanks. The waste characterization for this unit includes diesel fuel.

4.19.4 Potential for Release/Known Releases

According to 1983 Environmental Science and Engineering, the valves on the drain lines from the enclosed berm are normally closed and are screened whenever rainwater accumulates inside the enclosed area. If no contamination is visible, then the drain lines are opened, allowing the water to drain into the sewer or drainage ditch. No spills greater than 1000 gallons have been reported (Environmental Science and Engineering 1983). Routine drips at all four loading areas have resulted in stained soil (Georgia Department of Natural Resources 1989). Potential for release to the soil from within the concrete berm is low while potential for release to soil outside the berm from spills is high.

4.19.5 Proposed Work and Sample Analyses

4.19.5.1 General

The following work is proposed for the Phase I investigation for the Evans Army Heliport POL Storage Facility (FST-029):

- 1) This site has two 250,000-gallon diesel tanks (aboveground) that are enclosed in a berm approximately 5 feet high. Soil samples will be collected from inside the berm and outside the berm (Figure 4.41A).
- 2) Samples will also be collected at the off-loading areas and the on-loading points.
- 3) An investigation into all known spill events, their locations and quantities released will be performed and a list provided of the available information.

4.19.5.2 Soil Boring and Monitor-Well Installation Plan

Three soil sample sets inside and three sample sets outside the berm will be taken. Two additional soil samples will be collected at the off-loading and on-loading areas. Soil samples will be collected from every hand auger bucket during installation of the boring. Soil samples will be collected from the ground surface to the water table. Each sample will be screened in the field with an OVA-FID. The one sample that yields the highest reading or appears contaminated will be retained for analysis. If none of the samples appear to be contaminated, the first sample above the water table will be retained for testing. These soil borings will be installed by using hand-auger methods. The borings will be installed to a depth of 2-3 feet into the saturated zone of the surficial sand aquifer in accordance with the Field Sampling Approach (Section 6.0).

4.19.5.3 Field Sampling Plan

In accordance with the GA EPD's recommendations, the six soil samples collected from inside and outside the berm will be submitted for analysis of VOCs by EPA Method 8240, TPH by EPA Method 8015, and all TCLP constituents. The two soil samples to be collected from the off and on-loading areas will be analyzed as stated above. One extra TCLP sample set will be

collected for matrix analyses at the laboratory. One trip blank will be submitted for analysis. Refer to Table 6.1 for sampling summary. Field sampling will follow procedures found in the QAPP (Attachment A) and the Field Sampling Approach (Section 6.0).

4.20 The Recirculating Wash Impoundment "Birdbath" (FST-030).

4.20.1 Site Description

The Recirculating Wash Impoundment or "Birdbath" is located on the western edge of the cantonment area off State Route 144 (Figure 4.42). Wastewater from the vehicle washing facility is received in this concrete lined impoundment. Sludge (grease and sand) is removed and disposed of in the on-site landfill approximately every six months.

4.20.2 Previous Investigations

No previous investigations of this site have been performed. The site was mentioned and briefly described in the 1989 GA EPD RFA Report.

4.20.3 Waste Characterization

Grease and oil is generated in the wash waters during the cleaning of equipment in the "Birdbath". The wastewater is run through a sand filter. The waste characterization includes grease, sludge, and probably waste oil, non-hazardous used standard type II solvent, and used hydraulic fluid.

4.20.4 Potential for Release/Known Releases

No information is available that documents a release of waste to the environment. The "Birdbath" is reported to be a closed system so that the potential for a release to the surrounding soil or ground water is low.

4.20.5 Proposed Work and Sample Analyses

4.20.5.1 General

The following work is proposed for the Phase I investigation for the Recirculating Wash Impoundment (FST-030):

- 1) A sample of the sludge will be taken from both sludge holding impoundments (Figure 4.42A).
- 2) A description of the site will be prepared and provided to the state for review.

4.20.5.2 Field Sampling Plan

One sample set will be taken of the sludge from each of the two sludge holding impoundments. The samples will be submitted for analysis of VOCs by EPA Method 8240, all TCLP constituents, TPH by EPA Method 8015 and pH by EPA Methods 9040/9045. Two extra TCLP sample sets will be submitted for matrix and duplication/split analysis at the laboratory. Refer to Table 6.1 for sampling summary. Field sampling will follow procedures found in the QAPP (Attachment A) and the Field Sampling Approach (Section 6.0). Recommendations for any further sampling or monitoring wells will be included in the Phase I RFI Report.

4.21 The DEH Asphalt Tanks (FST-031)

4.21.1 Site Description and History

The DEH Asphalt tanks are located in the south cantonment area near Utility Street and the railroad tracks (Figure 4.43). Three 20,000-gallon above-ground tanks surrounded by an earthen berm are found at this site. There is also a much smaller tank nearby that is also above ground. The tanks held cut-back asphalt for use on the base. The time of operation for these tanks is unknown.

4.21.2 Previous Investigations

No previous investigations have been conducted at this site. The tanks were briefly described in the 1989, GA EPD RFA report, Environmental Priorities Initiative Preliminary Assessment of Fort Stewart, Georgia.

4.21.3 Waste Characterization

The only material stored at this site is asphalt. Therefore, the waste characterization for the DEH asphalt tanks includes asphalt and its associated by-products.

4.21.4 Potential for Releases/Known Releases

No releases are known or have been documented. The potential for release to the soils surrounding the tanks outside the berm are low. The potential for release through spillage to the soils inside the berm is high.

4.21.5 Proposed Work and Sample Analyses

4.21.5.1 General

The following work is proposed for the Phase I investigation for the DEH Asphalt Tanks (FST-031):

- 1) Soil samples will be taken inside the berm and outside the berm (Figure 4.43A).
- 2) A description of the site will be prepared and provided to the state for review.

4.21.5.2 Soil Boring and Monitor-Well Installation Plan

Three soil sample sets will be collected near the tank inside the berm and three soil sample sets will be collected outside the berm. All samples will be collected from within the upper 1 foot of soil. All soil samples will be screened with an OVA-FID or OVA-PID. These soil samples will be collected using hand-auger methods in accordance with the Field Sampling Approach (Section 6.0) and the QAPP (Attachment A).

4.21.5.3 Field Sampling Plan

The six soil samples will be submitted for analysis of VOCs by EPA Method 8240, TPH by Method 8015 and pH by EPA Methods 9040/9045. One trip blank will be submitted for analysis. Refer to Table 6.1 for sampling summary. Field sampling will follow procedures found in the QAPP (Attachment A) and the Field Sampling Approach (Section 6.0). Recommendations for any further sampling or monitoring wells will be included in the Phase I RFI Report.

4.22 The Supply Diesel Tank (FST-032)

4.22.1 Site Description and History

The supply diesel tank is located on the south side of the cantonment area, between buildings 1123 and 1121 (Figure 4.44). There is one above-ground tank at this site which is enclosed in a berm. The period of time that this tank has been in operation is unknown.

4.22.2 Previous Investigations

No previous investigations have been conducted at this site. The tank was mentioned and briefly described in the 1989 GA EPD RFA report.

4.22.3 Waste Characterization

Diesel fuel is the only product stored in this tank. Therefore, the waste characterization of the supply diesel tanks includes diesel constituents.

4.22.4 Potential for Releases/Known Releases

No releases is known or has been documented. The potential for release to the soil outside the berm is low while potential for release through spillage to soil inside the berm is high.

4.22.5 Proposed Work and Sample Analyses

4.22.5.1 General

The following work is proposed for the Phase I investigation:

- 1) Soil samples will be collected next to the tank inside and outside of the berm (Figure 4.44A).
- 2) A description of the current site conditions will be submitted to the state.

4.22.5.2 Soil Boring and Monitor-Well Installation Plan

Three soil sample sets next to the tank inside the berm and three soil sample sets outside the berm will be collected. All soil samples will be collected from the upper 1 foot of soil. Soil samples will be collected from every hand auger bucket during installation of the boring. Each sample will be screened in the field with an OVA-FID. The one sample that yields the highest reading or appears contaminated will be retained for analysis. If none of the samples appear to be contaminated, the last sample collected will be retained for testing. We propose to install these soil borings by using hand-auger methods in accordance with the Field Sampling Approach (Section 6.0).

4.22.5.3 Field Sampling Plan

The samples will be submitted for analysis of VOCs by EPA Method 8240 and TPH by EPA Method 8015. Refer to Table 6.1 for sampling summary. Field sampling will follow procedures found in the QAPP (Attachment A) and the Field Sampling Approach (Section 6.0). 5.0 QUALITY ASSURANCE PROJECT PLAN

To ensure the quality of the field and laboratory data produced during the implementation of the RFI, a Generic Quality Assurance Program Plan (QAPP) has been prepared. The QAPP has been prepared according to the guidelines set forth by the U.S. Environmental Protection Agency (EPA) in "Interim Guidelines and Specifications for Preparing Quality Assurance Project Plans", (QAMS-005/80), EPA. The QAPP has been structured as a generic document to provide general guidance to the field and laboratory personnel concerning methodologies for sampling and analysis of environmental media, proper record keeping protocols, data quality objectives, and procedures for data review. The detailed plan is included at Attachment A.

6.0 FIELD SAMPLING APPROACH

6.1 Waste Characterization

Waste characterization involves collecting data that describe the physical and chemical aspects of waste materials and the matrix in which they are contained. These data are valuable for identifying indicator parameters, possible migration pathways, and monitoring procedures, as well as determining the nature and scope of corrective measures which may be applied. Several ground water, surface water, soil, and sludge samples will be submitted for analyses (Table 6.1).

Waste characterization may be implemented whenever it is necessary to identify the types of waste disposed at a SWMU. In contrast, waste characterization may be limited when the SWMU of concern is no longer active and the waste cannot be sampled. Additional waste characterization, not outlined in this work plan, will be identified in Phase II, if necessary.

Waste Characterization will describe methods that may be used to (1) collect data through review of available information, (2) collection of additional information, and (3) characterize the physical and chemical properties of the materials.

6.1.1 Review of Existing Data and Records

Identification of the types and constituents of waste materials will be made, where possible, through the examination of the references from the SOW. These records may include the following:

- waste characterization data used for permit applications,
- past state or sampling analyses,
- records of disposal practices and operating procedures, referenced in documents listed in the SOW,
- reports on environmental assessments, referenced in documents listed in the SOW,
- information concerning age and period of operation of facility, referenced in documents listed in the SOW, and
- information from past or present employees.

* Note: More surface water samples may be required if surface drains into a ditch(es) prior to Mill Creek.

** 75 tanks will be tightness tested.

Note: RCRA metals EPA Methods are 6010 + 7470/7471 + 7060 + 7421 + 7740.

Note: pH EPA Methods are 9040/ 9045.

Note: Specific conductivity EPA Method is 9050.

6.1.2 Site Inspection

A site inspection will be made to generally define existing conditions. Information gained from the site inspection may include, but will not be limited to the following:

- integrity of waste containment,
- location and size of areas of concern,
- location of drainage features and possible conduits for migration,
- locations of discharge points,
- level of site security, and
- facility sketch map of all areas of concern.

6.1.3 Collection of Additional Information

In some cases, adequate characterization of wastes will be made by evaluating existing records or data on operating procedures. When verifiable information on wastes at a site are not available, but required to be investigated in the Scope of Work, additional data collection activities will be required.

6.2 Soil and Sediment Investigation

The objective of the soil and sediment investigation is to provide a framework for site-specific identification of the nature and extent of soil and sediment contamination at the facility. The potential for inter-media transfer of releases from soil and sediment to other media is significant. Contaminated soil and sediment can be major sources of contamination to ground water, air, subsurface gas, and surface water.

The work involved in the investigation will be to review existing data and conduct field studies that will help define the nature and magnitude of the existing contamination. The information included in this plan are excerpts from the Interim Final RCRA Facility Investigation Guidance Manual, EPA, May 1989.

6.2.1 Sampling

The extent and location of sampling required for waste characterization will depend on professional judgement concerning the need for additional information. The extent of information gathered during the review of available data and site inspection, as well as the complexity of the site and environmental media, will play roles in determining the extent and locations of sampling.

The sampling methods utilized will be appropriate for the type of material and item being sampled. Waste materials may include solids, sludges, and liquids; items may include drums, sludge drying beds, and surface impoundments. Details of sampling procedures are described in the Quality Assurance Project Plan (Attachment A).

Analytical parameters will be chosen based on extent of available information. Analyzing for broad indicator parameters such as total organic halogens or pH may be useful when there is little or no knowledge of what materials may be present. Whenever possible, analyses for specific constituents of concern will be conducted. Analyses may be conducted by a laboratory or in the field, when appropriate.

Appropriate sample collection and preservation techniques are specified in the QAPP (Attachment A). Specific measures must be taken to store and preserve samples to minimize their degradation. The sampling techniques described below are commonly used with a minimum of soil disturbance. Soil sampling methods will commonly vary with the depth of interest. Surficial sampling in the upper 6 inches of soil can usually be accomplished with simple tools, including shovels, spatulas, soil punches, and ring samplers. Constituents that have moved further downward in the soil profile often require tools such as tube samplers and augers. Manually operated tools are commonly useful to about 8 feet in depth, depending on the soil type. Below this depth, hydraulically or mechanically driven equipment generally is needed.

6.2.2 Chemical Analyses

Soil samples may be collected for laboratory chemical analyses. The methodology for preparation of samples and analytical techniques are described in the QAPP (Attachment A).

Field analyses may be conducted on soil samples, including determination of volatile organic vapors using either an OVA or a photoionizer such as an HNu or Photovac instrument. The OVA uses a flame ionization detector to measure organic vapors. Organic material that burns in a hydrogen flame can be detected. The OVA is most sensitive to aliphatic and aromatic hydrocarbons. It is less sensitive to alcohols, ketones, and aldehydes. The instrument's sensitivity decreases with increasing chlorine substitution to various hydrocarbons. The OVA is only moderately sensitive to many volatile organic halocarbons and is relatively insensitive to trihalomethanes and carbon tetrachloride. The ambient (background) reading will be subtracted from the field measurement of the sample. The sample will also be screened with a carbon filter probe which isolates the amount of methane the sample registers. The methane value will be subtracted from the unfiltered value where hydrocarbons may be detected producing a resultant value.

The HNu and Photovac uses a photoionization technique to detect selected organic vapors in the sampled air stream. These instruments primarily respond to organic compounds containing double or triple bonds such as alkenes (ethene, propene, etc.), chlorinated alkenes (trichloroethene, tetrachloroethene, various dichloroethenes), aromatic hydrocarbons (benzene, xylene, toluene), as well as many ketones and aldehydes.

6.3 Hydrogeologic Investigation

The objective of the hydrogeologic investigation is to provide an outline for conducting the necessary investigations to (1) determine the nature of the subsurface geology and aquifer characteristics at the facility, and (2) determine the presence or absence of releases.

Based on the review of existing data and reports and the results of field reconnaissance activities, a Phase I field investigation program will be undertaken to obtain site-specific information on the hydrogeology, including lithology, stratigraphy, structure, presence of aquifer(s) and confining unit(s), aquifer characteristics, physical and chemical characteristics of the formation, water levels, recharge/discharge, water quality, and ground-water use.

6.3.1 Drilling

Hollow-stem auger drilling involves the use of hollow auger flights to drill a borehole. The method is rapid and extremely effective in most unconsolidated, but cohesive sediments. The major advantage to this method is that fluids are not introduced to the hole. Also, it is the ideal method for drilling to obtain undisturbed samples for geotechnical and chemical analyses. The best method for collecting a soil sample using auger drilling is by driving a split spoon through the center of the auger flight. Maximum penetration using hollow stem auger is generally 75 to 100 feet below land surface.

6.3.2 Formation Sampling

Formation sampling provides a means to examine the physical and mineralogical properties of the geologic media. Methods of formation sampling include drilling or augering soil borings and excavating test pits; and sampling using split-spoons, augers, and Shelby tubes or collecting grab samples. Samples may be described and field analyzed or sent to a laboratory for geotechnical or chemical analyses. Appropriate sample collection and preservation techniques are specified in the QAPP (Attachment A).

6.3.3 Monitoring Wells

The purpose of monitoring wells will be to supplement existing wells in defining ground-water flow rates and direction, aquifer characteristics, and to assist in determining if releases are present. Monitoring wells will be installed in the unconsolidated surficial sediments. All drilling development and sampling equipment will be decontaminated in accordance with the QAPP (Attachment A).

Boreholes for installation of surficial monitoring wells will be of sufficient diameter to permit a minimum of 2 inches of annular space when the well is installed. The surficial monitoring wells will be completed at varying depths depending on the lithology encountered; depths of surficial wells will be approximately 30 feet and less. Split-spoon samples will be collected continuously to 10 feet below land surface (bls) and at 5-foot intervals thereafter to the total depth of the well. Soil samples for grain-size distribution and moisture content will be collected with the split-spoon samplers.

The physical characteristics of the samples obtained will be described in detail on lithologic logs using the United Soil Classification System. Soil samples will be classified based on the results of geotechnical laboratory analyses. A detailed well construction log will be prepared for each well.

The surficial monitoring wells will be constructed using 5 feet or more of new, 2-inch-diameter, factory-slotted or continuous wrap, polyvinyl chloride (PVC) well screen with Schedule 40, threaded, flush joint, PVC casing extending to 3 feet above land surface. The PVC casings will conform to the requirements of ASTM-D 1785 and will carry the seal of the National Sanitation Foundation. Each well will be fitted with a vented PVC cap and protection as outlined in the field sampling plans for each SWMU.

The screen length, screen size, and screened interval of the well will be selected so that the completed monitoring well yields quantities of water and samples that are representative of the selected zone of interest. Consideration will be given to the effects of precipitation at Fort Stewart which causes great fluxation of the water-table surface. The screen length will be 10 feet to insure that the water table remains within the screened interval at all times.

The annular space between the borehole and screen (approximately sized for the selected well screen) will be filled with uniformly graded silica sand from the bottom of the hole to approximately 2 feet above the top of the well screen using the tremie method. The tremie method incorporates the use of a drop pipe placed in the annular space of the well through which sand can be placed at the desired depth.

A bentonite seal with minimum thickness of 1 foot will be placed above the filter pack in each well to prevent downward migration of cement grout (Figure 6.1). The seal, consisting of tamped bentonite pellets or bentonite slurry also will be installed by the tremie method. The remaining annular space above the bentonite will be sealed by pressure grouting with cement grout to land surface. The cement grout will consist of a mixture of Portland Type I cement (ASTM-C 150) and water in the proportion not to exceed seven gallons of clean water per bag of cement (94 pounds). Additionally, 5 to 10 percent by weight of bentonite powder will be added to the grout to prevent shrinking and to control the heat of hydration during grouting, which can cause the casing to warp.

FIGURE 6.1 PROPOSED MONITOR WELL CONSTRUCTION

Boreholes will be drilled as near to plumb and true as possible to assist in proper casing alignment, sand pack, and cement seal. Precautions will be used during the drilling and well construction to prevent the entry of foreign material into the well. The well casing will extend to 2 to 3 feet above grade and will be surrounded by a large diameter steel casing set into a concrete pad. The steel casing will have a lockable cap. The concrete pad will be a minimum of 3 feet by 3 feet wide and 4 inches thick, sloped away from the well.

After the completion of each monitoring well, but no sooner than 48 hours after grouting is completed, well development will be conducted. The wells will be developed by alternately swabbing (with a surge block) and pumping or bailing. No acids, dispersing agents, or explosives will be used in the well. Development will continue until pH, conductivity, and turbidity have stabilized. If the well yield is too low to permit continuous pumping or bailing, the well will be alternatively swabbed, pumped, or bailed dry, and allowed to recharge at least five well volumes.

6.3.4 Ground-water Sampling

6.3.4.1 Well Survey

Elevations at sites within one-half mile of the cantonment area will be surveyed to a common datum point. Elevations at sites greater than one-half mile distance from the cantonment area will be surveyed to a temporarily established bench mark.

6.3.4.2 Water-Level Measurements

The static water-level will be measured prior to purging and sampling the ground water. The static water level will be determined to the nearest 0.01 foot. An electronic water-level indicator (M-scope) or chalked steel tape will be used for the water-level measurement. Duplicate measurements will be recorded for each well and referenced to the survey point (top of well casing). Devices used to measure ground-water levels shall be calibrated to 0.01 feet per 10-foot length. Before each use, these devices shall be prepared according to the manufacturer's instructions (if appropriate) and checked for obvious damage. These devices shall be decontaminated after each use as described in Appendix A. Calibration and maintenance data shall be recorded in a logbook.

6.3.4.3 Purging the Well

After a water-level measurement has been taken, the monitoring well will be purged to remove the standing water. Purging can be accomplished by pumping or bailing. If pumping is used, the end of the intake tube will be positioned just below the static water level. The intake is then lowered as the water level drops so that the water in the well casing is completely and efficiently removed. The intake tube will be removed from the well before suction has been discontinued. Bailing the well is acceptable. However, if a bailer is employed, extreme care will be taken in lowering the bailer into the well to avoid "surging" the water in the casing. Three to five volumes of water will be evacuated from each well so that a representative sample of formation water is collected.

6.3.4.4 Field Measurements

After purging the well, a water sample will be collected to obtain measurements of pH, temperature, and conductivity. Before obtaining these measurements, the field instrumentation must be properly calibrated in accordance with the QAPP (Attachment A).

6.3.4.5 Sample Collection

After obtaining the field measurements, the monitoring well will be sampled for the parameters of interest. Geraghty & Miller will obtain samples for organic analyses with a bottom-filling Teflon™ bailer. Sampling for dissolved metals involves mounting an in-line 0.45μ membrane filter to a filter stand and connecting the stand to the outlet of the peristaltic pump.

Samples of the ground water present in the screened interval will be collected by lowering the pump intake or Teflon™ bailer, as appropriate, to a depth below land surface (bls) that is approximately equal to the depth to the center of the well screen. This procedure will be initiated so that the sample collected is representative of ground water at the depth of the screened interval.

Sample containers, preservation techniques, and shipping procedures are specified in the QAPP (Attachment A). Decontamination procedures for the pumping and sampling equipment also are detailed in Attachment A.

7.0 HEALTH AND SAFETY PLAN

This Health and Safety Plan (HASP) has been prepared by Geraghty & Miller, Inc. to be used during the RCRA Facility Investigation at Fort Stewart. The Resume of Negotiation Proceedings indicated that all drilling, sampling, and other field activities will be performed in Level D protection. Therefore, this plan is designed for Level D protection only. In the event that conditions at a site necessitate a higher measure of personnel protection, work will stop at that site and the COE Project Manager will be notified. Work conducted under higher levels of protection will be handled under contract modifications. The elements of this Level D HASP are described in detail in Attachment B.
